1. Forward

The CP/M macro assembler, called `MAC`, reads assembly language statements from a diskette file and produces a “hex” format object file on the diskette suitable for processing in the CP/M environment, and is upward compatible from the standard CP/M non-macro assembler (see the Digital Research manual entitled “*CP/M Assembler (ASM) User’s Guide*”). The facilities of `MAC` include assembly of Intel 8080 micro computer mnemonics, along with assembly-time expressions, conditional assembly, page formatting features, and a powerful macro processor which is compatible with the standard Intel definition (`MAC` implements the mid-1977 revision of Intel’s definition, which is not compatible with previous versions). In addition, `MAC` will accept most programs prepared for the Processor Technology Software #1 assembler, normally requiring only minor modifications.

The macro assembler is supplied on a CP/M non-system diskette, along with a number of standard library files. The macro assembler requires approximately 12K of machine code and table space, along with an additional 2.5K of I/O buffer space. Since the BDOS portion of CP/M is coresident with `MAC`, the minimum usable memory size for `MAC` is approximately 20K. Any additional memory adds to the available symbol table area, thus allowing larger programs to be assembled.

Upon receiving the `MAC` diskette, you should follow the steps given below

- (a) Place the `MAC` diskette into drive B, with a CP/M system diskette in drive A. Copy the `MAC.COM` to drive A from drive B using `PIP` (see the *CP/M Features and Facilities Guide* for `PIP` operation).
- (b) Copy the `SAMPLE.ASM` program from drive B to drive A using the `PIP` program.
- (c) Remove the `MAC` diskette from drive B, and retain the diskette for future backup (there are a number of “`LIB11`” files which may be useful at a later time).
- (d) Type “`MAC SAMPLE`” to execute the macro assembler (see Listing 2-1). The macro assembler should load and print the signon message. Upon completion, the final program address is printed, followed by the “use factor” which indicates that the assembly is complete.
- (e) Type the “`SAMPLE.PRN`” and “`SAMPLE.SYM`” files, and compare with Listing 2-1 to ensure that the assembler is executing properly, thus completing the `MAC` test.

This manual is organized in three major sections. The first section describes the simple assembler facilities of `MAC` which involve 8080 mnemonic forms, expressions, and conditional assembly, similar to the discussion found in the *ASM User’s Guide*. If you are familiar with `ASM`, you may wish to skip over the first section, and start reading Section 6. The second portion of this manual, beginning with Section 6, describes the `MAC` macro facilities in some detail. Again, if you are familiar with macros, you may wish to briefly skim these sections, and refer primarily to

the examples to get the “flavor” of the `MAC` facility. Section 10 discusses macro applications, where common macro forms and programming practices are discussed. Again, it is useful to skim the examples and refer back to the explanations for detailed discussions of each program.

2. Macro Assembler Operation Under CP/M

The user must first prepare a source program containing assembly language statements using the ED program under CP/M (see the Digital Research manual “*CP/M Context Editor (ED) User’s Guide*”), and then submit the assembly language file for processing under MAC. Although the user may specify certain options (described under “Assembly Parameters”), the usual invocation of MAC is simply

MAC *filename*

where “*filename*” corresponds to the assembly language file which was prepared using ED, with an assumed (and unspecified) file type of “.ASM”. Upon completion of the translation process, MAC leaves a file called “*filename*.HEX” containing the machine code in Intel hexadecimal format which can subsequently be loaded (see the LOAD command in the “*CP/M Features and Facilities*” manual), or tested under the CP/M debugger (see the “*CP/M Dynamic Debugging Tool (DDT) User’s Guide*”). In addition to the HEX file, MAC also prepares a file named “*filename*.PRN” which contains an annotated source listing, along with a file called “*filename*.SYM” which contains a sorted list of symbols defined in the program.

Listing 2-2 provides an example of the output from MAC for a sample assembly language program which is stored on the diskette under the name SAMPLE.ASM. The macro assembler is executed by typing “MAC SAMPLE” followed by a carriage return. Upon completion, the PRN, SYM, and HEX files will appear as shown in the figure. The assembler listing file (PRN) includes a 16 column annotation at the left which shows the values of literals, machine code addresses, and generated machine code. Note that an equal sign (=) is used to denote literal values (see the EQU directive) to avoid confusion with machine code addresses. In all cases, output files contain tab characters (ASCII CTRL-I) wherever possible in order to conserve diskette space. Tab positions are assumed to be placed at every eight columns of the output line.

```

      org      100h      ;transient program area
bdos   equ      0005h    ;bdos entry point
wchar  equ      2        ;write character function
;      enter with ccp's return address in the stack
;      write a single character (?) and return
      mvi c,wchar      ;write character function
      mvi e,'?'        ;character to write
      call bdos        ;write the character
      ret              ;return to the ccp
      end      100h    ;start address is 100h
```

Listing 2-1: **Source Program:** SAMPLE.ASM

```

0100          ORG      100H      ;TRANSIENT PROGRAM AREA
0005 =        BDOS      EQU     0005H  ;BDOS ENTRY POINT
0002 =        WCHAR     EQU     2      ;WRITE CHARACTER FUNCTION
          ;      ENTER WITH CCP'S RETURN ADDRESS IN THE STACK
          ;      WRITE A SINGLE CHARACTER (?) AND RETURN
0100 0E02      MVI C,WCHAR      ;WRITE CHARACTER FUNCTION
0102 1E3F      MVI E,'?'        ;CHARACTER TO WRITE
0104 CD0500    CALL BDOS        ;WRITE THE CHARACTER
0107 C9        RET              ;RETURN TO THE CCP
0108          END      100H      ;START ADDRESS IS 100H

Listing 2-4: **Assembly HEX Output File:** SAMPLE.HEX

3. Program Format

A program acceptable as input to the macro assembler consists of a sequence of statements of the form

line# label operation operand comment

where any or all of the elements may be present in a particular statement. Each assembly language statement is terminated by a carriage return and line feed (the line feed is inserted automatically by the ED program when the file is prepared), or with the character “!” which is treated as an end of line by the assembler. Thus, multiple assembly language statements can be written on the same physical line if separated by exclamation marks.

Statement elements are delimited by a sequence of one or more blank or tab characters. Tab characters are preferred since the program element alignment is automatically maintained in the output line at every eighth column, without requiring extra blanks in the file. This not only conserves source file space, but also reduces the listing file size since the tab characters are included in the PRN file. The tab characters are not actually expanded until the file is printed or typed at the console.

The *line#* is an optional decimal integer value representing the source program line number, which is allowed on any source line in case the program is prepared with a line editor which uses line numbers at the beginning of each statement. In an cases, the optional *line#* is ignored by the assembler.

The label field takes the form

identifier or *identifier:*

and is optional, except where noted in particular statement types. The *identifier* is a sequence of alphanumeric characters (alphabetic characters, question marks ('?'), commercial at-signs ('@'), and numbers) where the first character is alphabetic (including '?', and '@'). Identifiers can be freely used by the programmer to label elements such as program steps and assembler directives, but cannot exceed 16 characters in length. All characters are insignificant in an identifier, except for the embedded dollar sign '\$' which can be used to improve readability of the name. Further, all lower case alphabetic characters are treated as if they are upper case in an identifier. Note that the ':' following the identifier in a label is optional (to maintain compatibility between the Intel and Processor Technology versions). Thus, the following are all valid instances of labels

x	xy	Long\$name
X?	xy1:	Longer\$name'data
x1x2	@123:	??@abcDEF

Gamma	@GAMMA	?
		ARE\$WE\$HERE?

x234\$5678\$9012\$3456:

The *operation* field contains an assembler directive (pseudo operation), 8080 machine operation code, or a macro invocation with optional parameters. The **pseudo operations** and **machine operation codes** are described below, while the **macro calls** are delayed for later discussion.

The *operand* field of the statement, in general, contains an expression formed from constant and label operands, with arithmetic, logical, and relational operations upon these operands. Again, the complete details of properly formed expressions are given in sections which follow.

The *comment* field is denoted by a leading “;” character, and contains arbitrary characters until the next real or logical end of line. These character are read, listed, and otherwise ignored in the assembly process. In order to maintain compatibility with other assemblers, MAC also treats statements which begin with a “*” in the first position as comment lines.

The assembly language program is thus a sequence of statements of the above form, terminated optionally by an `END` statement. All statements following the `END` are ignored by the assembler.

4. Forming the Operand

In order to completely describe the operation codes and pseudo operations, it is necessary to first present the form of the operand field, since it is used in nearly all statements. Expressions in the operand field consist of simple operands (labels, constants, and reserved words), combined into properly formed sub-expressions by arithmetic and logical operators. The expression computation is carried out by the assembler as the assembly proceeds. Each expression produces a 16-bit value during the assembly. Further, the number of significant digits in the result must not exceed the intended use. That is, if an expression is to be used in a byte move immediate (see the `MVI` instruction), the absolute value of the operand must fit within an 8-bit field. The restrictions on the expression significance are given with the individual instructions.

4.1. Labels

As discussed above, a label is an identifier which occurs on a particular statement. In general, the label is given a value determined by the type of statement which it precedes. If the label occurs on a statement which generates machine code or reserves memory space (e.g., a `MOV` instruction or a `DS` pseudo operation), then the label is given the value of the program address which it labels. If the label precedes an `EQU` or `SET`, then the label is given the value which results from evaluating the operand field. In the case of a macro definition, the label is given a text value (i.e., a sequence of ASCII characters) which is the body of the macro definition. With the exception of the `SET` and `MACRO` pseudo operations, an identifier can label only one statement.

When a (non-macro) label appears in the operand field, its 16-bit value is substituted by the assembler. This value can then be combined with other operands and operators to form the operand field for a particular instruction. When a macro identifier appears in the operation field of the statement, the text which is stored as the value of the macro name is substituted in place of the name. In this case, the operand field of the statement contains “actual parameters” which are substituted for “dummy parameters” in the body of the macro definition. The exact mechanisms for definition, invocation, and substitution of macro text are given in later sections.

4.2. Numeric Constants

A numeric constant is a 16-bit value in one of several number bases. The base, called the radix of the constant, is denoted by a trailing radix indicator. The radix indicators are:

- B** binary constant (base 2)
- O** octal constant (base 8)
- Q** octal constant (base 8)
- D** decimal constant (base 10)
- H** hexadecimal constant (base 16)

Q is an alternate radix indicator for octal numbers since the letter o is easily confused with the digit 0. Any numeric constant which does not terminate with a radix indicator is assumed to be a decimal constant.

A constant is thus composed as a sequence of digits, followed by an optional radix indicator, where the digits are in the appropriate range for the radix. That is, binary constants must be composed of 0 and 1 digits, octal constants can contain digits in the range 0 - 7, while decimal constants contain decimal digits. Hexadecimal constants contain decimal digits as well as hexadecimal digits A through F (corresponding to the decimal numbers 10 through 15). Note, however, that the leading digit of a hexadecimal constant must be a decimal digit in order to avoid confusing a hexadecimal constant with an identifier (a leading 0 will always suffice). A constant composed in this manner will produce a binary number which can be contained within a 16-bit counter, truncated on the right by the assembler. Similar to identifiers, imbedded 11t symbols are allowed within constants to improve their readability. Finally, the radix indicator is translated to upper case if a lower case letter is encountered. The following are all valid instances of numeric constants:

1234	1234D	1100B	1111\$0000\$1111\$0000B
1234H	OFFFEH	3377O	33\$77\$22Q
3377o	0fe3h	1234d	Offffh

4.3. Reserved Words

There are several reserved character sequences which have predefined meanings in the operand field of a statement. The names of 8080 registers are given below which, when encountered, produce the corresponding value.

Symbol	Value
A	7
B	0
C	1
D	2
E	3
H	4
L	5
M	6
SP	6
PSW	6

Table 4-1: Reserved Characters

Again, lower case names have the same values as their upper case equivalents. Machine instructions can also be used in the operand field, and result in their internal codes. In the case of instructions which require operands, where the specific operand becomes a part of the binary bit pattern of the instruction (e.g., `MOV A,B`), the value of the instruction is the bit pattern of the instruction with zeroes in the optional fields. For example, the statement

```
LXI H,MOV
```

assembles an `LXI H` instruction with an operand equal to `40H` (which is the value of the `MOV` instruction with zeroes as operands).

When the symbol “\$” appears in the operand field (not imbedded within identifiers and numbers), its value becomes the address of the beginning of the current instruction. For example, the two statements

```
X:    JMP X
```

and

```
      JMP $
```

both produce a jump instruction to the current location. As an exception, the symbol at the beginning of a logical line can introduce assembly formatting instructions (see “assembly parameters”).

4.4. String Constants

String constants represent sequences of graphic ASCII characters, and are represented by enclosing the characters within apostrophe symbols ('). All strings must be fully contained within the current physical line, with the ' ' character within strings treated as an ordinary string character. Each individual string must not exceed 64 characters in length, otherwise an error is reported. The apostrophe character itself can be included within a string by representing it as a double apostrophe (the two keystrokes " ' ' "), which become a single apostrophe when read by the assembler.

Note that particular operation codes may require that the string length be no longer than one or two characters. The LXI instruction, for example, will accept a character string operand of one or two characters, while the CPI instruction will accept only a one character string. The DB instruction, however, allows strings of length zero through 64 characters in its list of operands. In the case of single character strings, the value becomes the 8-bit ASCII code for the character (without case translation), while two character strings produce a 16-bit value, with the second character as the low order byte, and the first character as the high order byte. The string constant 'A' for example, is equivalent to 41H, while the two character string 'AB' produces the 16-bit value 4142H. The following strings are valid in various MAC statements:

'A' 'AB' 'ab' 'c' ' ' 'she said "hello"'

There is one special case which must be considered inside string constants. As discussed in later sections, the character "&" can be used to cause evaluation of dummy arguments within macro expansions when they occur inside of string quotes. The exact details of the substitution process will be given in the discussion of macro definition and call statements.

4.5. Arithmetic, Logical, and Relational Operators

The operands described above can be combined in normal algebraic notation using any combination of properly formed operands, operators, and parenthesized expression. The operators recognized by MAC in the operand field are given below. In general, the letters *a* and *b* represent operands which are treated as 16-bit unsigned quantities in the range 0-65535. All arithmetic operators (+, -, *, /, MOD, SHL, and SHR) produce a 16-bit unsigned arithmetic result, the relational operators (EQ, LT, LE, GT, GE, and NE) produce a true (0FFFFH) or false (0000H) 16-bit result, and the logical operators (NOT, AND, OR, and XOR) operate bit-by-bit on their operand(s) producing a 16-bit result of 16 individual bit operations. The HIGH and LOW functions always produce a 16-bit result with a high order byte which is zero.

a+b produces the arithmetic sum of *a* and *b*, *+b* is *b*

a-b produces the arithmetic difference between *a* and *b*, *-b* is 0-*b*

a*b is the unsigned magnitude multiplication of *a* by *b*

a/b is the unsigned magnitude division of a by b
 $a \text{ MOD } b$ is the remainder after division of a by b
 $a \text{ SHL } b$ produces a shifted left by b , with zero right fill
 $a \text{ SHR } b$ produces a shifted right by b , with zero left fill
NOT b is the bit-by-bit logical inverse of b
 $a \text{ EQ } b$ produces true if a equals b , false otherwise
 $a \text{ LT } b$ produces true if a is less than b , false otherwise
 $a \text{ LE } b$ produces true if a is less or equal to b , false otherwise
 $a \text{ GT } b$ produces true if a is greater than b , false otherwise
 $a \text{ GE } b$ produces true if a is greater or equal to b , false otherwise
 $a \text{ AND } b$ produces the bitwise logical AND of a and b
 $a \text{ OR } b$ produces the bitwise logical OR of a and b
 $a \text{ XOR } b$ produces the logical exclusive OR of a and b
HIGH b is identical to $b \text{ SHR } 8$ (high order byte of b)
LOW b is identical to $b \text{ AND } \text{OFFH}$ (low order byte of b)

In general, all computations are performed during the assembly process as 16-bit unsigned operations, as described above. The resulting expression must fit the operation code in which it is used. For example, the expression used in an ADI (add immediate) instruction must fit into an 8-bit field, and thus the high order byte must be zero. If the computed value does not fit the field, the assembler produces a value error for that statement. As an exception to this rule, 8-bit values which would normally be considered “negative” are allowed in 8-bit fields under the following conditions: if the program attempts to fill an 8-bit field with a 16-bit value which has all 1’s in the high order byte, and the “sign bit” is set, then the high order byte is truncated and no error is reported. This particular condition arises when a negative sign is placed in front of a constant. The value -2, for example, is defined (and computed) as $0 - 2$ which produces the 16-bit value `OFFFEH`, where the high order byte (`OFFH`) contains extended sign bits which are all 1’s, while the low order byte (`FEH`) has the sign bit set. Thus, the following instructions do not produce value errors in MAC:

ADI -1 ADI -15 ADI -127 ADI -128 ADI 0FF80H

while the following instructions do produce value errors:

ADI 256 ADI 32768 ADI -129 ADI 0FF0H

The special operator `NUL` is used in conjunction with macro definition and expansion operations, and must be the last operator in the operand field, preceding only a single operand. The use and effects of the `NUL` operator are delayed until the discussion of macros.

Expressions can generally be formed from simple operands such as labels, numeric constants, string constants, and machine operation codes, or fully enclosed parenthesized expressions such as:

- 10+209
- 10H+37Q
- L1/3
- (L2 + 4) SHR 3
- ('a' and 5fh) + '0'
- (('BB') + B) OR (PSW + M)
- (1 + (2+C)) shr (A-(B + 1))
- (HIGH A) SHR 3

where blanks and tabs are ignored between the operators and operands of the expression.

4.6. Precedence of Operators

As a convenience to the programmer, MAC assumes that operators have a relative precedence of application which allows expressions to be written without nested levels of parentheses. The resulting expression has assumed parentheses which are defined by this relative precedence. The order of application of operators in unparenthesized expressions is listed below. Operators listed first have highest precedence, and are applied first in an unparenthesized expression. Operators listed last have lowest precedence, and are applied last. Operators listed on the same line have equal precedence, and are applied from left to right as they are encountered in an expression:

*	/	MOD	SHL	SHR	
		+	-		
EQ	LT	LE	GT	GE	NE
		NOT			
		AND			
		OR	XOR		
		HIGH	LOW		

Thus, the expressions shown below are equivalent:

- $a * b + c$ produces $(a * b) + c$
- $a + b * c$ produces $a + (b * c)$
- $a \text{ MOD } b * c \text{ SHL } d$ produces $(a \text{ MOD } b) * c \text{ SHL } d$
- $a \text{ OR } b \text{ AND NOT } c + d \text{ SHL } e$ produces $a \text{ OR } (b \text{ AND } (\text{NOT } (c + (d \text{ SHL } e))))$

Balanced parenthesized sub-expressions can always be used to override the assumed parentheses, and thus the last expression above could be rewritten to force application of operators in a different order as shown below:

`(a OR b) AND (NOT c) + d SHL e`

resulting in the assumed parentheses:

`(a OR b) AND ((NOT c) + (d SHL e))`

Note that an unparenthesized expression is well-formed only if the expression which results from inserting the assumed parentheses is well-formed.

As a notational convenience, the following are equivalent:

<code><</code>	LT
<code><=</code>	LE
<code>=</code>	EQ
<code><></code>	NE
<code>>=</code>	GE
<code>></code>	GT

5. Assembler Directives

Assembler directives are used to set labels to specific values during assembly, perform conditional assembly, define storage areas, and specify starting addresses in the program. Each assembler directive is denoted by a pseudo operation which appears in the operation field of the statement. The acceptable pseudo operations are given below.

- ORG** sets the program or data origin
- END** terminates the physical program
- EQU** performs a numeric “equate”
- SET** performs a numeric “set” or assignment
- IF** begins conditional assembly
- ELSE** is an alternate to a previous IF
- ENDIF** marks the end of conditional assembly
- DB** defines data bytes or strings of data
- DW** defines words of storage (double bytes)
- DS** reserves uninitialized storage areas
- PAGE** defines the listing page size for output
- TITLE** enables pages titles and options

In addition to those listed above, there are several pseudo operations which are used in conjunction with the macro processing facilities. Specifically, the **MACRO**, **EXITM**, **ENDM**, **REPT**, **IRPC**, **IRP**, **LOCAL**, and **MACLIB** operations are reserved words, and are fully described in separate sections which deal with macro processing. The non-macro pseudo operations are detailed below.

5.1. The **ORG** Directive

The **ORG** statement takes the form

label **ORG** *expression*

where “*label*” is an optional program label (i.e., an identifier followed by an optional “:”), and “*expression*” is a 16-bit expression consisting of operands which are defined previous to the **ORG** statement. The assembler begins machine code generation at the location specified in the expression. There can be any number of **ORG** statements within a particular program, and there are no checks to ensure that the programmer is not redefining overlapping memory areas. Note that most programs written for CP/M begin with an **ORG 100H** statement which causes machine code generation to begin at the base of the CP/M transient program area.

If a *label* is specified in the **ORG** statement, then the *label* takes on the value given by the *expression*, which is the next machine code address to assemble. This label can then be used in the *operand* field of other statements to represent this *expression*.

5.2. The END Directive

The END statement is optional in an assembly language program, but if present it must be the last statement. All statements following the END are ignored. The two forms of the END statement are:

label END

label END *expression*

where the *label* is optional. If the first form is used, the assembly process stops, and the default starting address of the program is taken as 0000. Otherwise, the expression is evaluated and becomes the program starting address. This starting address is included in the last record of the Intel format machine code “HEX” file which results from the assembly. Thus most CP/M assembly language programs end with the statement

```
END 100H
```

resulting in the default starting address of 100H, which is the beginning of the transient program area (TPA).

5.3. The EQU Directive

The EQU (equate) statement is used to name synonyms for particular numeric values. The form is

label EQU *expression*

where the *label* must be present, and must not label any other statement. The assembler evaluates the expression and assigns this value to the identifier given in the *label* field. The identifier is usually a name which describes the value in a more human-oriented manner. Further, this name can be used throughout the program as a parameter for certain functions. Suppose, for example, that data received from a Teletype appears on a particular input port, and data is sent to the Teletype through the next output port in sequence. The series of equate statements that could be used to define these ports for a particular hardware environment are shown below.

```
TTYBASE EQU 10H      ;BASE TTY PORT
TTYIN    EQU TTYBASE  ;TTY DATA IN
TTYOUT   EQU TTYBASE+1 ;TTY DATA OUT
```

At a later point in the program, the statements which access the Teletype could appear as:

```
IN  TTYIN      ;READ TTY DATA TO A
OUT TTYOUT     ;WRITE DATA FROM A
```

making the program more readable than if the absolute I/O port addresses had been used. If the hardware environment is later redefined to start the Teletype communications ports at 7FH instead of 10H, the first statement need only be changed to:

```
TTYBASE EQU 7FH      ;BASE PORT NUMBER FOR TTY
```

and the program can be reassembled without changing any other statements.

5.4. The SET Directive

The SET statement is similar to the EQU, taking the form

label EQU expression

except that the label, taken as a variable name, can occur on other SET statements within the program. The expression is evaluated and becomes the current value associated with the label. Thus, unlike the EQU statement where a label takes on a single value throughout the program, the SET statement can be used to assign different values to a name at different parts of the program. In particular, the SET statement gives the label a value which is valid from the current SET statement to the point where the label occurs on the next SET statement. The use of SET is similar to the EQU, except that SET is used more often to control conditional assembly within macros.

5.5. The IF, ELSE, and ENDIF Directives.

The IF, ELSE, and ENDIF directives define a range of assembly language statements which are to be included or excluded during the assembly process. The IF and ENDIF statements alone can be used to bound a group of statements to be conditionally assembled, as shown below:

```
IF expression
statement#1
statement#2
...
statement#n
ENDIF
```

Upon encountering the IF statement, the assembler evaluates the expression following the IF (all operands in the expression must be defined ahead of the IF statement). If the least significant bit of the expression is 1 then statement#1 through statement#n are assembled. If the least significant bit of the expression is zero, then the statements are listed but not assembled.

Conditional assembly is often used to write a single “generic” program which includes a number of possible alternative subroutines or program segments, where only a few of the possible alternatives are to be included in any given assembly. Listing 5-5 and Listing 5-6 give an example of such a program. Assume that a console device (either a Teletype or CRT) is connected to an 8080 microcomputer through I/O ports. Due to the electronic environment, the “current loop” Teletype is connected through ports 10H and 11H, while the ‘IRS-2321’ CRT is connected through ports 20H and 21H. The program continually loops, reading and writing console characters. A single program is shown which, when the condition is properly set, produces a program which operates with either a Teletype (TTY is TRUE), or with a CRT (TTY is

FALSE), but not both. Listing 5-5 shows an assembly for the Teletype environment, while Listing 5-6 shows the assembly for a CRT-based system. Note that the leftmost 16 columns are left blank by the assembler when statements are skipped due to a false condition.

```

CP/M MACRO ASSEM 2.0      #001      Teletype Echo Program

FFFF =      TRUE      EQU      0FFFFH      ;DEFINE "TRUE"
0000 =      FALSE     EQU      NOT TRUE     ;DEFINE "FALSE"
FFFF =      TTY      EQU      TRUE      ;SET TTY ON
0010 =      TTYBASE   EQU      10H      ;BASE OF TTY PORTS
0020 =      CRTBASE   EQU      20H      ;BASE OF CRT PORTS
                        IF      TTY      ;ASSEMBLE TTY PORTS
                                TITLE  'Teletype Echo Program'
0010 =      CONIN     EQU      TTYBASE     ;CONSOLE INPUT
0011 =      CONOUT    EQU      TTYBASE+1   ;CONSOLE OUT
                                ENDIF
                        IF      NOT TTY    ;ASSEMBLE CRT PORTS
                                TITLE  'CRT Echo Program'
                                CONIN     EQU      CRTBASE     ;CONSOLE IN
                                CONOUT    EQU      CRTBASE+1   ;CONSOLE OUT
                                ENDIF
                        ;
0000 DB10      ECHO:    IN      CONIN      ;READ CONSOLE CHARACTER
0002 D311      OUT     CONOUT    ;WRITE CONSOLE CHARACTER
0004 C30000    JMP      ECHO
0007                                END

```

Listing 5-5: **Conditional Assembly:** with TTY="TRUE"

```

CP/M MACRO ASSEM 2.0      #001      CRT Echo Program

FFFF =      TRUE      EQU      0FFFFH      ;DEFINE "TRUE"
0000 =      FALSE     EQU      NOT TRUE     ;DEFINE "FALSE"
0000 =      TTY      EQU      FALSE     ;SET TTY OFF
0010 =      TTYBASE   EQU      10H      ;BASE OF TTY PORTS
0020 =      CRTBASE   EQU      20H      ;BASE OF CRT PORTS
                        IF      TTY      ;ASSEMBLE TTY PORTS
                                TITLE  'Teletype Echo Program'
                                CONIN     EQU      TTYBASE     ;CONSOLE INPUT
                                CONOUT    EQU      TTYBASE+1   ;CONSOLE OUT
                                ENDIF
                        IF      NOT TTY    ;ASSEMBLE CRT PORTS
                                TITLE  'CRT Echo Program'
0020 =      CONIN     EQU      CRTBASE     ;CONSOLE IN
0021 =      CONOUT    EQU      CRTBASE+1   ;CONSOLE OUT
                                ENDIF
                        ;
0000 DB20      ECHO:    IN      CONIN      ;READ CONSOLE CHARACTER
0002 D321      OUT     CONOUT    ;WRITE CONSOLE CHARACTER
0004 C30000    JMP      ECHO
0007                                END

```

Listing 5-6: **Conditional Assembly:** with TTY="FALSE"

The ELSE statement can be used as an alternative to an IF statement, and must occur between the IF and ENDIF statements. The form is:

```

IF      expression
    statement#1
    statement#2
    ...
    statement#n
ELSE
    statement#n+1

```

```

statement#n+2
...
statement#m
ENDIF

```

If the expression produces a non-zero (true) value, then statements 1 through n are assembled, as before. In this case, however, statements n+1 through m are skipped in the assembly process. When the expression produces a zero value (false), statements 1 through n are skipped, while statements n+1 through m are assembled. As an example, the conditional assembly shown in Listing 5-6 could be rewritten as shown in Listing 5-7.

```

CP/M MACRO ASSEM 2.0      #001      CRT Echo Program

FFFF =      TRUE      EQU      0FFFFH ;DEFINE "TRUE"
0000 =      FALSE     EQU      NOT TRUE;DEFINE "FALSE"
0000 =      TTY      EQU      FALSE  ;SET TTY OFF
0010 =      TTYBASE   EQU      10H   ;BASE OF TTY PORTS
0020 =      CRTBASE   EQU      20H   ;BASE OF CRT PORTS
                        IF      TTY   ;ASSEMBLE TTY PORTS
                        TITLE   'Teletype Echo Program'
                        CONIN    EQU   TTYBASE      ;CONSOLE INPUT
                        CONOUT   EQU   TTYBASE+1    ;CONSOLE OUT
                        ELSE     ;ASSEMBLE CRT PORTS
                        TITLE   'CRT Echo Program'
0020 =      CONIN     EQU      CRTBASE      ;CONSOLE IN
0021 =      CONOUT    EQU      CRTBASE+1    ;CONSOLE OUT
                        ENDIF
;
0000 DB20      ECHO:   IN      CONIN      ;READ CONSOLE CHARACTER
0002 D321      OUT     CONOUT     ;WRITE CONSOLE CHARACTER
0004 C30000    JMP      ECHO
0007                                END

```

Listing 5-7: **Conditional Assembly:** using "ELSE"

Properly balanced IF's, ELSE's, and ENDIF's can be completely contained within the boundaries of outer encompassing conditional assembly groups. The structure outlined below shows properly nested IF, ELSE, and ENDIF statements:

```

IF exp#1
group#1
IF exp#2
group#2
ELSE
group#3
ENDIF
group#4
ELSE
group#5
IF exp#3
group#6
ENDIF
group#7
ENDIF

```

where group 1 through 7 are sequences of statements to be conditionally assembled, and exp#1 through exp#3 are expressions which control the conditional assembly. If exp#1 is true, then group#1 and group#4 are always assembled, and groups 5, 6, and 7 will be skipped. Further, if exp#1 and exp#2 are both true, then group#2 will also be included in the assembly, otherwise group#3 will be included. If exp#1 produces a false value, groups 1, 2, 3, and 4 will be skipped, and groups 5 and 7 will always be assembled. If under these circumstances, exp#3 is true then group#6 will also be included with 5 and 7, otherwise it will be skipped in the assembly. A structure similar to this is shown in Listing 5-8, where literal true/false values are used to show conditional assembly selection.

Conditional assembly of this sort can be nested up to eight levels (i.e., there can be up to eight pending IF's or ELSE's with unresolved ENDIF's at any point in the assembly), but usually becomes unreadable after two or three levels of nesting. The nesting level restriction also holds, however, for pending IF's and ELSE's during macro evaluation. Nesting level overflow will produce an error during assembly.

```

FFFF =      TRUE  EQU 0FFFFH    ;DEFINE "TRUE"
0000 =      FALSE EQU NOT TRUE  ;DEFAULT "FALSE"

      IF      FALSE
      MVI     A,1
      IF      TRUE
      MVI     A,2
      ELSE
      MVI     A,3
      ENDIF
      MVI     A,4
      ELSE
0000 3E05    MVI     A,5
      IF      TRUE
0002 3E06    MVI     A,6
      ELSE
      MVI     A,7
      ENDIF
0004 3E08    MVI     A,8
      ENDIF
0006         END

```

Listing 5-8: **Sample Program:** using Nested IF, ELSE, and ENDIF

5.6. The DB Directive.

The DB directive allows the programmer to define initialized storage areas in single precision (byte) format. The statement form is

label DB *expression#1*, *expression#2*, ..., *expression#n*

where the *label* is optional, and *expression#1* through *expression#n* are either expressions which produce 8-bit values (the high order eight bits are zero, or the high order nine sign bits are one's), or are ASCII strings of length no greater than 64 characters each. There is no practical restriction on the number of expressions included on a single source line. The expressions are evaluated and placed sequentially into the machine code following the last program address generated by the assembler. String characters are similarly placed into

memory starting with the first character and ending with the last character. Strings of length greater than two characters cannot be used as operands in more complicated expressions (i.e., they must stand alone between the commas). Note that ASCII characters are always placed in memory with the high order (parity) bit reset to zero. Further, recall that there is no translation from lower to upper case within strings. The optional label can be used to reference the data area throughout the program. Examples of valid DB statements are:

```
data:   DB   0,1,2,3,4,5,6
        DB   data and Offh,5,377Q,1+2+3+4
signon: DB   'please type your name:',cr,lf,0
        DB   'AB' SHR 8, 'C', 'DE' AND 7FH
        DB   HIGH data, LOW (signon GT data)
```

5.7. The DW Directive

The DW statement is similar to the DB statement except double precision (two byte) words of storage are initialized. The form is:

label DW expression#1, expression#2, ..., expression#n

where the *label* is optional, and *expression#1* through *expression#n* are expressions which produce 16-bit values. Note that ASCII strings of length one or two characters are allowed, but strings longer than two characters are disallowed. In all cases, the data storage is consistent with the 8080 processor: the least significant byte of the expression is stored first in memory, followed by the most significant byte. The following DW statements are examples of properly formed statements:

```
doub:   DW   Offefh, doub+4,signon-$,255+255
        DW   'a', 5, 'AB', 'CD', doub LT signon
```

5.8. The DS Directive.

The DS statement is used to reserve an area of uninitialized memory, and takes the form:

label DS expression

where the *label* is optional. The assembler begins subsequent code generation after the area reserved by the DS. Thus, the DS statement given above has exactly the same effect as the statement sequence:

```
label:  EQU   $           ;CURRENT CODE LOC
        ORG   $+expression ;MOVE PAST AREA
```

5.9. The PAGE and TITLE Directives.

The PAGE and TITLE pseudo operations give the programmer control over the output formatting which is sent to the PRN file (or directly to the printer device). The forms for the PAGE statement are:

PAGE

and

`PAGE expression`

If the `PAGE` statement stands alone, as in the first case above, the output page is ejected to the top of form (i.e., an ASCII CTRL-L (form feed) is sent to the output file). The form feed is sent after the statement with `PAGE` has been printed, thus the `PAGE` command is often issued directly ahead of major sections of an assembly language program, such as a group of subroutines, to cause the next statement to appear at the top of the following printer page.

The second form of the `PAGE` command is used to specify the output page size. In this case, the expression which follows the `PAGE` pseudo operation determines the number of output lines to be printed on each page. If the expression is zero, there are no page breaks, and the print file is simply a continuous sequence of annotated output lines. If the expression is non-zero, then the page size is set to the value of the expression, and form feeds are issued to cause page ejects when this count is reached for each page. The assembler initially assumes that

`PAGE 56`

is in effect, thus producing a page eject at the beginning of the listing, and at each 56 line increment.

The `TITLE` directive takes the form:

`TITLE string-constant`

where the string-constant is an ASCII string, enclosed in apostrophes, which does not exceed 64 characters in length. If a `TITLE` pseudo operation is given during the assembly, each page of the listing file is prefixed with the title line, preceded by a standard MAC header. The title line thus appears as:

`CP/M MACRO ASSEM n.n #ppp string-constant`

where *n.n* is the MAC version number, *ppp* is the page number in the listing, and *string-constant* is the string given in the `TITLE` pseudo operation. MAC initially assumes that the `TITLE` operation is not in effect. When specified, the title line, along with the blank line which follows the title, are not included in the line count for the page. Normally, no more than one `TITLE` statement is included in a particular program. Similarly, no more than one `PAGE` statement with the expression option is normally included. If a `TITLE` statement is included, and the symbol table is being appended to the PRN file (see Section 11), then the SYM file also contains the specified title at the beginning of the symbol listing, with page breaks given by either the default or specified value of the `PAGE` statement.

5.10. A Sample Program using Pseudo Operations.

Listing 5-9 demonstrates the various pseudo operations available in MAC. The sample program, called “typer” is intended to operate in the CP/M environment by performing the simple function of selecting one of three messages for output at the console. This program is created using the ED program, then assembled using MAC, and then placed into “.COM” file format using the CP/M LOAD function. Given that these steps have been accomplished, typer is executed at the console command processor level of CP/M by typing one of the commands:

```
typer a
typer b
typer c
```

to select message A, B, or C for printing. The typer program loads under the CCP, and jumps to the label START where the 8080 stack is initialized. The typer program then prints its signon message, which would appear as:

```
'typer' version 1.0
```

The program then retrieves the first character typed at the console following the command typer which should be one of the letters A, B, or C. If one of these letters is not specified, then typer “reboots” the CP/M system to give control back to the CCP. If a valid letter is provided, typer selects one of the three messages (MESS@A, MESS@B, or MESS@C) and prints it at the console before returning to CP/M.

Note that the TITLE and PAGE statements are used to produce a title at the beginning of each page (form feeds were necessarily suppressed here), with a page size of 20 lines, excluding the title lines. A number of EQU statements are used at the beginning to improve readability of the program. Note that the exclaim symbol (!) is used throughout the program to allow several simple assembly language statements on the same line. Although multiple statements make the program more compact, they often decrease the overall readability of the source program. Note also that the program terminates without the END statement, which is only necessary if a starting address is specified. The END statement is often included, however, to maintain compatibility with other assemblers.

The DB statements labelled by SIGNON contain simple strings of characters, as well as expressions which produce single byte values. The DW statement following TABLE defines the base address of each string (corresponding to A, B, and C). Finally, the DS statement at the end of the program reserves space for the stack defined within the typer program.

```

CP/M MACRO ASSEM 2.0      #001      Typer Program

                                TITLE  'Typer Program'

Listing 5-9: Sample Program: typer

6. Operation Codes

Operation codes, found in the *operation* field of the statement, form the principal components of assembly language programs. In general, MAC accepts all the standard mnemonics for the Intel 8080 microcomputer, which are given in detail in the Intel manual “8080 Assembly language Programming Manual.” Labels are optional on each input line and, if included, take the value of the instruction address immediately before the instruction is issued by the assembler. The individual operators are listed briefly in the following sections in order to be complete, although it is understood that the Intel documents should be referenced for exact operator details. In the discussion which follows, the operation codes are placed into categories for discussion purposes, followed by a sample assembly which shows the hexadecimal codes produced for each operation. The following notation is used throughout the discussion:

e3 represents a 3-bit value in the range 0-7 that can be one of the predefined registers A, B, C, D, E, H, L, M, SP, or PSW.

e8 represents an 8-bit value in the range 0-255. (recall that signed 8-bit values are also allowed in the range -128 through +127)

e16 represents a 16-bit value in the range 0-65535.

where e3, e8, and e16 can themselves be formed from an arbitrary combination of operands and operators in a well-formed expression. In some cases, the operands are restricted to particular values within the range, such as the PUSH instruction. These cases will be noted as they are encountered.

6.1. Jumps, Calls, and Returns

The Jump, Call, and Return instructions allow several different forms that test the condition flags set in the 8080 microcomputer CPU. The forms are shown in Table 6-2.

Form	Bit Value	Example	Meaning
JMP	e16	JMP L1	Jump unconditionally to label
JNZ	e16	JNZ L2	Jump on nonzero condition to label
JZ	e16	JZ 100H	Jump on zero condition to label
JNC	e16	JNC L1+4	Jump no carry to label
JC	e16	JC L3	Jump on carry to label
JPO	e16	JPO \$+8	Jump on parity odd to label

Form	Bit Value	Example	Meaning
JPE	<i>e16</i>	JPE L4	Jump on even parity to label
JP	<i>e16</i>	JP GAMMA	Jump on positive result to label
JM	<i>e16</i>	JM A1	Jump on minus to label
CALL	<i>e16</i>	CALL S1	Call subroutine unconditionally
CNZ	<i>e16</i>	CNZ S2	Call subroutine on nonzero condition
CZ	<i>e16</i>	CZ 100H	Call subroutine on zero condition
CNC	<i>e16</i>	CNC SI+4	Call subroutine if no carry set
CC	<i>e16</i>	CC S3	Call subroutine if carry set
CPO	<i>e16</i>	CPO \$+8\$	Call subroutine if parity odd
CPE	<i>e16</i>	CPE \$4	Call subroutine if parity even
CP	<i>e16</i>	CP GAMMA	Call subroutine if positive result
CM	<i>e16</i>	CM b1\$c2	Call subroutine if minus flag
RST	<i>e3</i>	RST 0	Programmed restart, equivalent to CALL 8 * <i>e3</i> , except one byte call
RET	-	RET	Return from subroutine
RNZ	-	RNZ	Return if nonzero flag set
RZ	-	RZ	Return if zero flag set
RNC	-	RNC	Return if no carry
RC	-	RC	Return if carry flag set
RPO	-	RPO	Return if parity is odd
RPE	-	RPE	Return if parity is even
RP	-	RP	Return if positive result

Form	Bit Value	Example	Meaning
RM	-	RM	Return if minus flag is set

Table 6-2: Jumps, Calls, and Returns

Listing 6-10 shows the hexadecimal codes for each instruction, along with a short comment on each line which describes the function of the instruction.

6.2. Immediate Operand Instructions

Several instructions are available that load single- or double-precision registers or single-precision memory cells with constant values, along with instructions that perform immediate arithmetic or logical operations on the accumulator (register A). Table 6-3 describes the immediate operand instructions.

Several instructions are available which load single or double precision registers or single precision memory cells with constant values, along with instructions which perform immediate arithmetic or logical operations on the accumulator (register A).

Form and Bit Value	Example	Meaning
MVI e3,e8	MVI B, 255	Move immediate data to register A, B, C, D, E, H, L, or M (memory)
ADI e8	ADI 1	Add immediate operand to A without carry
ACI e8	ACI 0FFH	Add immediate operand to A with carry
SUI e8	SUI L + 3	Subtract from A without borrow (carry)
SBI e8	SBI L AND 11B	Subtract from A with borrow (carry)
ANI e8	ANI \$ AND 7FH	Logical and A with immediate data
XRI e8	XRI 1111\$0000B	Exclusive-or A with immediate data
ORI e8	ORI L AND 1+1	Logical-or A with immediate data
CPI e8	CPI 'a'	Compare A with immediate data, same as SUI except register A not changed.
LXI e3,e16	LXI B, 100H	Load extended immediate to register pair. e3 must be equivalent to B, D, H, or SP.

Table 6-3: Immediate Operand Instructions

The “move immediate” instruction takes the form:

MVI e3,e8

where e3 is the register to receive the data given by the value e8. The expression e3 must produce a value corresponding to one of the registers A, B, C, D, E, H, L, or the memory location M which is addressed by the HL register pair.

The “accumulator immediate” operations take the form:

ADI e8 ACI e8 SUI e8 SBI e8
ANI e8 XRI e8 ORI e8 CPI e8

where the operation is always performed upon the accumulator using the immediate data value given by the expression e8.

The “load extended immediate” instructions take the form:

LXI e3,e16

where e3 designates the register pair to receive the double precision value given by e16. The expression e3 must produce a value corresponding to one of the double precision register pairs B, D, H, or SP.

Listing 6-11 shows the use of the accumulator immediate operations in an assembly language program, along with a short comment describing the use of each instruction.

                                L1:
0010                        END

```

Listing 6-11: **Assembly Listing:** Immediate Operand Instructions

6.3. Increment and Decrement Instructions

The 8080 provides instructions for incrementing or decrementing single- and double precision registers. The instructions are described in Table 6-4

Form and Bit Value	Example	Meaning
INR e3	INR E	Single-precision increment register. e3 produces one of A, B, C, D, E, H, L, or M (memory)
DCR e3	DCR A	Single-precision decrement register. e3 produces one of A, B, C, D, E, H, L, or M (memory)
INX e3	INX SP	Double-precision increment register pair. e3 must be equivalent to B, D, H, or SP.
DCX e3	DCX B	Double-precision decrement register pair. e3 must be equivalent to B, D, H, or SP.

Table 6-4: Increment and Decrement Instructions

Listing 6-12 shows a sample assembly language program which uses both single and double precision increment and decrement operations.

```

CP/M MACRO ASSEM 2.0      #001    INCREMENT AND DECREMENT INSTRUCTIONS

                                TITLE    'INCREMENT AND DECREMENT INSTRUCTIONS'

                                ;
                                ;
                                INSTRUCTIONS REQUIRE REGISTER (3-BIT) OPERAND
0000 1C                    INR      E          ;BYTE INCREMENT A,B,C,D,E,H,L,M
0001 3D                    DCR      A          ;BYTE DECREMENT A,B,C,D,E,H,L,M
0002 33                    INX      SP         ;16-BIT INCREMENT B,D,H,SP
0003 0B                    DCX      B          ;16-BIT DECREMENT B,D,H,SP
0004                      END

```

Listing 6-12: **Assembly Listing:** Increment and Decrement Instructions

6.4. Data Movement Instructions

A number of 8080 instructions are placed in this category which move data from memory to the CPU and from the CPU to memory. A number of register to register move operations are also included. The single precision “move register” instruction takes the form:

```
MOV e3,e3l
```

where e3 and e3l are expressions which each produce one of the single precision registers A, B, C, D, E, H, L, or M (corresponding to the memory location addressed by HL). In all cases, the register named by e3 receives the 8-bit value given by the register expression e3l. The instruction is often read as “move to register e3 from register e3l”. The instruction “MOV B,H” would thus be read as “move to register B from register H”. Note that the instruction MOV M,M is not allowed.

The single precision load and store extended operations take the form:

```
LDAX e3
```

```
STAX e3
```

where e3 is a register expression which must produce one of the double precision register pairs B or D. The 8-bit value in register A is either loaded (LDAX) or stored (STAX) from/to the memory location addressed by the specified register pair.

The load and store direct instructions operate either upon the A register for single precision operations, or upon the HL register pair for double precision operations, and take the forms:

```
LHLD e16
```

```
SHLD e16
```

```
LDA e16
```

```
STA e16
```

where e16 is an expression produces the memory address to obtain (LHLD, LDA) or store (SHLD, STA) the data value.

The stack pop and push instructions perform double precision load and store operations, with the 8080 stack as the implied memory address. The forms are:

POP e3

PUSH e3

where e3 must evaluate to one of the double precision register pairs PSW, B, D, or H.

The input and output instructions are also found in this category, even though they receive and send their data to the electronic environment which is external to the 8080 processor. The input instruction reads data to the A register, while the output instruction sends data from the A register. In both cases, the data port is given by the data value which follows the instruction:

IN e8

OUT e8

Various instructions are a part of the instruction set which transfer double precision values between registers and the stack. These instructions are:

XTHL

PCHL

SPHL

XCHG

Listing 6-13 lists these instructions in an assembly language program, along with a short comment on the use of each instruction.

Instructions that move data from memory to the CPU and from CPU to memory are given in Table 6-5.

Form and Bit Value	Example	Meaning
MOV e3,e3	MOV A,B	Move data to leftmost element from rightmost element. e3 produces one of A, B, C, D, E, H, L, or M (memory). Note: MOV M,M is disallowed
LDAX e3	LDAX B	Load register A from computed address. e3 must produce either B or D.
STAX e3	STAX D	Store register A to computed address. e3 must produce either B or D.
LHLD e16	LHLD L1	Load HL direct from location e16. Double-precision load to H and L.
SHLD e16	SHLD L5+x	Store HL direct to location e16. Double-precision store from H and L to memory.

Form and Bit Value	Example	Meaning
LDA <i>e16</i>	LDA GAMMA	Load register A from address <i>e16</i> .
STA <i>e16</i>	STA X3-5	Store register A into memory at <i>e16</i> .
POP <i>e3</i>	POP PSW	Load register pair from stack, set SP. <i>e3</i> must produce one of B, D, H, or PSW.
PUSH <i>e3</i>	PUSH B	Store register pair into stack, set SP. <i>e3</i> must produce one of B, D, H, or PSW.
IN <i>e8</i>	IN 0	Load register A with data from port <i>e8</i> .
OUT <i>e8</i>	OUT 255	Send data from register A to port <i>e8</i> .
XTHL	XTHL	Exchange data from top of stack with HL.
PCHL	PCHL	Fill program counter with data from HL.
SPHL	SPHL	Fill stack pointer with data from HL.
XCHG	XCHG	Exchange DE pair with HL pair.

Table 6-5: Data Movement Instructions

Listing 6-13: **Assembly Listing:** Various Register/Memory Moves

6.5. Arithmetic Logic Unit Operations

A number of instructions are included in the 8080 set which operate between the accumulator and single precision registers, including operations upon the A register and carry flag. The accumulator/register instructions are:

```

ADD e3
ADC e3
SUB e3
SBB e3
ANA e3
XRA e3
ORA e3
CMP e3

```

where e3 produces a value corresponding to one of the single precision registers A, B C, D, E, H, L, or M, where the M “register” is the memory location addressed by the HL register pair.

The accumulator/carry operations given below operate upon the A register, or carry bit, or both.

DAA
CMA
STC
CMC
RLC
RRC
RAL
RAR

The actual function of each instruction is listed in the comment line shown in Listing 6-14.

The last instruction of this group is the double precision add instruction which performs a 16-bit addition of a register pair (B, D, H, or SP) into the 16-bit value in the HL register pair, producing the 16-bit (unsigned) sum of the two values which is placed into the HL register pair. The form is:

DAD e3

6.6. Control Instructions

The four remaining instructions in the 8080 set are categorized as control instructions, and take the forms:

HLT
DI

EI

NOP

and are used to stop the processor (HALT), enable the interrupt system (EI), disable the interrupt system (DI), or perform a “no-operation” (NOP).

7. An Introduction to Macro Facilities

The fundamental difference between the Digital Research “ASM” and “MAC” assemblers is that ASM provides only the fundamental facilities for assembling 8080 operation codes, while MAC includes a powerful macro processing facility. In particular, MAC implements the industry standard Intel macro definition, which includes the following pseudo operations.

MACRO definitions allow groups of instructions to be stored and substituted in the source program, as the macro names are encountered. Definitions and invocations (macro “calls”) can be nested, symbols can be constructed through concatenation (using the special “&” operator), and locally defined symbols can be created (using the LOCAL pseudo operation). Macro parameters can be formed to pass arbitrary strings of text to a specific macro for substitution during expansion. In addition, the MACLIB (macro library) feature allows the programmer to define a particular set of macros, equates, and sets for automatic inclusion in a program. A macro library can contain an instruction set for another central processor, for example, which is not directly supported by the MAC built-in mnemonics. The macro library may also include general purpose input/output macros which are used in various programs which operate in the CP/M environment to perform peripheral or diskette I/O functions.

IRPC, IRP, and REPT pseudo operations provide repetition of source statements under control of a count or list of characters or items to be substituted each time the statements are re-read by the assembler. This feature is particularly useful in generating groups of assembly language statements with similar structure, such as a set of file control blocks where only the file type is changed in each statement.

In order to illustrate the power of a macro facility, consider the macro library shown in Listing 7-15, which is assumed to reside in a diskette file called “MSGLIB.LIB”. This macro library contains macro definitions which have standard instruction sequences for program startup, message typeout, and program termination. The program shown in Listing 7-16 provides an example of the use of this macro library. The assembly shown in Listing 7-16 lists both the macro calls and the statements in the macro expansions which generate machine code. The statements which are marked by ‘+1 in Listing 7-16 are generated from the macro calls, while the remaining statements are a part of the calling program.

```

Listing 7-16: **Sample Assembly:** using the MACLIB Facility

As an introduction to MAC features, the macro invocation

```
ENTCCP 10
```

in Listing 7-16 shows a specific expansion of ENTCCP (enter from CCP) which is defined in the macro library given in Listing 7-15. The macro call causes MAC to retrieve the definition (i.e., the text between MACRO and ENDM in Listing 7-15) and substitute this text following the macro call in Listing 7-15. This particular macro performs the following function: upon entry to the program from the CCP, the stack pointer (SP) is saved into a variable called “@ENTSP” for later retrieval. The stack pointer is then reset to a local area for the remainder of the program execution. The size of the local stack is defined by the macro parameter which is named in the macro definition as SSIZE (see Listing 7-15), and filled-in at the call with the value 10. The result is that the ENTCCP macro reserves space for a local stack of SSIZE=10 double bytes (2 * 10 bytes) and, after setting up the stack, branches around this reserved area to continue the program execution.

Consider also the special macro statements which are used in Listing 7-15 within the body of the ENTCCP macro. The “local” statement defines the label START which is used within the macro

body. Generally, each `LOCAL` statement causes the macro assembler to construct a unique symbol (starting with “??”) each time it is encountered. Thus, multiple macro calls reference unique labels which do not interfere with one another. To continue the example, `ENTCCP` also contains a conditional assembly statement which uses the “`NUL`” operator, which is used to test whether a macro parameter has been supplied or not. In this case, the `ENTCCP` macro could be invoked by:

```
ENTCCP
```

with no actual parameter, resulting in a default stack size of 32 bytes. If this seems confusing, don’t be concerned at this point because the individual sections which follow give exact details and examples.

The `TYPEOUT` macro provides a more complicated example of macro use. Note that this macro contains a redefinition of itself within the macro body. That is, the structure of `TYPEOUT` is:

```
TYPEOUT  MACRO  ?MESSAGE
        . . .
TYPEOUT  MACRO  ??MESSAGE
        . . .
        ENDM
        . . .
        ENDM
```

where the outer definition of `TYPEOUT` completely encloses the inner definition. The outer definition is active upon the first invocation of `TYPEOUT`, but upon completion, the nested inner definition becomes active.

In order to see the use of such a nested structure, consider the purpose of the `TYPEOUT` macro. Each time it is invoked, `TYPEOUT` prints the message sent as an actual parameter at the console device. The `typeout` process, however, can be easily handled with a short subroutine. Upon the first invocation, we would like to include the subroutine “`inline`,” and then simply call this subroutine on subsequent invocations of `TYPEOUT`. Thus, the outer definition of `TYPEOUT` defines the utility subroutine, and then redefines itself so that the subroutine is called, rather than including another copy of the utility subroutine.

It should be noted that macro definitions are stored in the symbol table area of the assembler and thus each macro reduces the remaining free space. As a result, `MAC` allows “double semicolon” comments which indicate that the comment itself is to be ignored and not stored with the macro. Thus, comments with a single semicolon are stored with the macro and appear in each expansion while comment with two preceding semicolons are listed only when the macro is defined.

Listing 7-16 gives three examples of `TYPEOUT` invocations, with three messages which are sent as actual parameters. Note that the `LOCAL` statement causes a unique label to be created (??0002)

in the place of “PASTSUB” which is used to branch around the utility subroutine which is included inline between addresses 0126H and 0133H. The utility subroutine is then called, followed by another jump around the console message which is also included inline. Note, however, that subsequent invocations of TYPEOUT use the previously included utility subroutine to type their messages. Again, this may seem confusing, but it is worthwhile studying this example before continuing into the exact details of macro definition and invocation in order to gain some insight into macro facilities.

It should also be noted that, although the example shown here concentrates all macro definitions in a separate macro library, it is often the case that macros are defined in the mainline (.ASM) source program. In fact, many programs which use macros do not use the external macro library facility at all.

There are many applications of macros which will be examined throughout the remainder of this manual. Specifically, macro facilities can be used to simplify the programming task by “abstracting” from the primitive assembly language levels. That is, the programmer can define macros which provide more generalized functions that are allowed at the pure assembly language level, such as macro languages for a given applications (see Section 11), improved control facilities, and general purpose operating systems interfaces. The remainder of this manual first introduces the individual macro forms, then presents several uses of the macro facilities in realistic applications.

8. Inline Macros

The simplest macro facilities involve the REPT (repeat), IRPC (indefinite repeat character), and IRP (indefinite repeat) macro groups. All these forms cause the assembler to repetitively re-read portions of the source program under control of a counter or list of textual substitutions. These groups are listed below in increasing order of complexity.

8.1. The REPT-ENDM Group

The REPT-ENDM group is written as a sequence of assembly language statements starting with the REPT pseudo operation, and terminated by an ENDM pseudo operation. The form is:

```
label:  REPT expression
statement-1
statement-2

statement-n
label: ENDM
```

where the *labels* are optional. The expression following the REPT is evaluated as a 16-bit unsigned count of the number of times that the assembler is to read and process statements 1 through *n* which are enclosed within the group.

Listing 8-17 shows an example of the use of the REPT group. In this case the REPT-ENDM group is used to generate a short table of the byte values 5, 4, 3, 2, and 1. Upon entry to the REPT, the value of NXTVAL is 5 which is taken as the repeat count (even though NXTVAL changes within the REPT). Note that the macro lines which do not generate machine code are not listed in the repetition, while the lines which do generate code are listed with a “+” sign after the machine code address. Full macro tracing is optional, however, using assembly parameters, as discussed in a later section.

In general, if a *label* appears on the REPT statement, its value is the first machine code address which follows. This REPT *label* is not re-read on each repetition of the loop. The optional label on the ENDM is re-read on each iteration and thus constant labels (not generated through concatenation or with the LOCAL pseudo operation) will generate phase errors if the repetition count is greater than 1.

Properly nested macros, including REPT's, can occur within the body of the REPT-ENDM group. Further, nested conditional assembly statements are also allowed, with the added feature that conditionals which begin within the repeat group are automatically terminated upon reaching the end of the macro expansion. Thus, IF and ELSE pseudo operations are not required to have their corresponding ENDIF when they begin within the repeat group (although the ENDIF is allowed).

```

```

Listing 8-17: **Sample Program:** Using the REPT Group

8.2. The IRPC-ENDM Group

Similar to the REPT group, the IRPC-ENDM group causes the assembler to re-read a bounded set of statements, taking the form

```

label:  IRPC identifier character-list
statement-1
statement-2
...
statement-n
label:  ENDM

```

where the *optional* labels obey the same conventions as in the REPT-ENDM group. The “identifier” is any valid assembler name, not including embedded “\$” separators, and “character-list” denotes a string of characters, terminated by a delimiter (space, tab, end-of-line, or comment).

The IRPC controls the re-read process as follows: the statement sequence is read once for each character in the character-list. On each repetition, a character is taken from the character-list and associated with the controlling identifier, starting with the first and ending with the last character in the list. Thus, an IRPC header of the form

```
IRPC ?X,ABCDE
```

re-reads the statement sequence which follows (to the balancing ENDM) a total of five times, once for each character in the list “ABCDE”. On the first iteration, the character “A” is associated with

the identifier “9X” and on the fifth iteration the letter “E” is associated with the controlling identifier.

On each iteration, the macro assembler substitutes any occurrence of the controlling identifier by the associated character value. Using the above IRPC header, an occurrence of “9X” in the bounds of the IRPC-ENDM group is replaced by the character “A” on the first iteration, and by “E” on the last iteration.

The programmer can use the controlling identifier to construct new text strings within the body of the IRPC by using the special “concatenation” operator, denoted by an ampersand ‘&’. Again using the above IRPC header, the macro assembler would replace “LAB&?X” by “LABA” on the first iteration, while “LABE” would be produced on the final iteration. The concatenation feature is most often used to generate unique label names on each iteration of the IRPC re-read process.

Note, however, that the controlling identifier is not normally substituted within string quotes, since the controlling identifier could quite possibly occur as a part of a quoted message. Thus, the macro assembler performs substitution of the controlling identifier when it is either preceded and/or followed by the ampersand operator. Further, recall that all alphabetic characters outside string quotes are translated to upper case, while no case translation occurs within string quotes. This requires that the controlling identifier be not only preceded or followed by the concatenation operator within strings, but must also be typed in upper case.

Listing 8-18 illustrates the use of the IRPC-ENDM group. Listing 8-18 shows the original assembly language program, before processing by the macro assembler. Note that the program is typed in both upper and lower case. Listing 8-19 shows the output from the macro assembler, with the lower case alphabetic characters translated to upper case. Three IRPC groups are shown in this example. The first IRPC uses the controlling identifier ILreg“ to generate a sequence of stack push operations which save the double precision registers BC, DE, and HL. Again note that the lines generated by this group are marked by a “+” sign following the machine code address.

```

;      construct a data table
;
;      save relevant registers
enter: irpc    reg,bdh
      push    reg      ;;save reg
      endm

;
;      initialize a partial ascii table
      irpc    c,lab$?@
data&c: db      '&C'
      endm

;
;      restore registers
      irpc    reg,hdb
      pop     reg      ;;recall reg
      endm
      ret
      end

```

Listing 8-18: **Source File:** IRPC Example

```

;      CONSTRUCT A DATA TABLE
;
;      SAVE RELEVANT REGISTERS
ENTER: IRPC    REG,BDH
      PUSH    REG      ;;SAVE REG
      ENDM
0000+C5      PUSH    B
0001+D5      PUSH    D
0002+E5      PUSH    H
;
;      INITIALIZE A PARTIAL ASCII TABLE
      IRPC    C,LAB$?@
DATA&C: DB      '&C'
      ENDM
0003+4C      DATA:  DB      'L'
0004+41      DATAA: DB      'A'
0005+42      DATAB:  DB      'B'
0006+24      DATA$: DB      '$'
0007+3F      DATA?: DB      '?'
0008+40      DATA@: DB      '@'
;
;      RESTORE REGISTERS
      IRPC    REG,HDB
      POP     REG      ;;RECALL REG
      ENDM
0009+E1      POP     H
000A+D1      POP     D
000B+C1      POP     B
000C C9      RET
000D          END

```

Listing 8-19: **Program Listing:** IRPC Example

8.3. The IRP-ENDM Group

The IRP (indefinite repeat) is similar in function to the IRPC, except that the controlling identifier can take on a multiple character value. The form of the IRP group is

```

label: IRP identifier,<cl-l,cl-2,...,cl-n>
statement-1
statement-2

```

```

    ...
statement-m
Label: ENDM

```

where the optional *labels* obey the conventions of the REPT and IRPC groups. The identifier controls the iteration as follows. On the first iteration, the character-list given by *cl-1* is substituted for the identifier wherever the identifier occurs in the bounded statement group (statements 1 through *m*). On the second iteration, *cl-2* becomes the value of the controlling identifier. Iteration continues in this manner until the last character-list, denoted by *cl-n*, is encountered and processed. Substitution of values for the controlling identifier is subject to the same rules as in the IRPC (note rules for substitution within strings and concatenation of text using the ampersand operator "&"). One should also note that controlling identifiers are always ignored within comments.

Listing 8-20 gives several examples of IRP groups. The first occurrence of the IRP in Listing 8-20 is a typical use of this facility to generate a "jump vector" at the beginning of a program or subroutine. The IRP assigns label names (INITIAL, GET, PUT, and FINIS) to the controlling identifier "9LAB" and produces a jump instruction for each label by re-reading the IRP group, substituting the actual label for the formal name on each iteration.

The second occurrence of the IRP group in Listing 8-20 points out substitution conventions within strings (for both IRPC and IRP groups). The controlling identifier "IS" takes on the values "A-ROSE" and "I?" on the two iterations of the IRP group, respectively. Note that the controlling identifier is replaced by the character-lists in the two cases "&IS" and "IM" inside the string quotes since they are both adjacent to the ampersand operator. Note further that "Ns&" is not replaced because the controlling identifier is typed in lower case, and there is no automatic translation to upper case within strings. The occurrences of "IS" within the comments are not substituted.

The last IRP group shows the effects of an empty character-list. The value of the controlling identifier becomes the null string of symbols and, in the cases where "?X" is replaced, produces the statement

```
DB
```

which produces no machine code, and is therefore not listed in the macro expansion. The three statements

```

DB '?x'
DB '?X'
DB '&'

```

appear in the expansions because the "?x" is typed in lower case (and thus is not replaced), the '?X' does not appear next to an ampersand in the string (and is thus not replaced), while in the

last case only one of the double ampersands is absorbed in the '&&?X&' string. In this last case, the two ampersands which surround "?X" are removed since they occur immediately next to the controlling identifier within the string.

Recall that substitution rules outside of string quotes and comments is much less complicated: the controlling identifier is replaced by the current character-list value whenever it occurs in any of the statements within the group. Further, the ampersand operator can be placed before or after the controlling identifier to cause the preceding or following text to be concatenated.

The actual forms for the character-lists (*cl*–1 through *cl*–*n*) are more general than stated here. In particular, bracket nesting is allowed as well as escape sequences to allow delimiters to be ignored. The exact details of character-list forms are discussed in the macro parameter sections.

```

;      CREATE A "JUMP VECTOR" USING THE IRP GROUP

0052          END

```

Listing 8-20: **Program Listing:** IRP Example

8.4. The EXITM Statement

The EXITM pseudo operation can occur within the body of a macro and, upon encountering the EXITM statement, the macro assembler aborts expansion of the current macro level. The EXITM pseudo operation occurs in the context

```

macro-heading
statement-1
label: EXITM
...
statement-n
ENDM

```

where the *label* is optional, and “*macro-heading*” denotes the REPT, IRPC, or IRP group heading as described above. The EXITM statement can also be used with the MACRO group, as discussed in later sections.

In order to be useful, the EXITM statement normally occurs within the scope of a surrounding conditional assembly operation. If the EXITM occurs in the scope of a false conditional test, the statement is ignored and macro expansion continues. If the EXITM occurs within the scope of a true conditional, the expansion stops at the point where the EXITM is encountered. Assembly statement processing continues after the ENDM of the group aborted by the EXITM statement.

Two examples of the EXITM statement are shown in Listing 8-21. This figure shows two IRPC's used to generate “DB” statements which do not exceed eight characters in length. These IRPC's might occur within the context of another macro definition, such as in the generation of CP/M file control block (FCB) names. In both cases, the variable “LEN” is used to count the number of filled characters. If the count ever reaches eight characters, the EXITM statement is assembled under a true condition, and the IRPC stops expansion.

The first IRPC generates the entire string “SHORT” since the length of the character-list is less than eight characters. Each evaluation of “LEN = 8” produces a false value and the EXITM is skipped. Thus, this IRPC terminates normally by exhausting the character-list through its five repetitions.

The second IRPC stops generation at the eighth character of the list “LONGSTRING” when the conditional “LEN EQ 8” produces a true value (note that “=” and “EQ” are equivalent operators), resulting in assembly of the EXITM statement. The EXITM causes immediate termination of the expansion process.

The second IRPC also contains a conditional assembly without the balancing ENDIF. In this case, the ENDIF is not required since the conditional begins within the macro body. The ENDM serves the dual purpose of terminating unmatched IF's as well as marking the physical end of the macro body.

```

;      SAMPLE USE OF THE EXITM STATEMENT WITH THE IRPC MACRO
;
;      THE FOLLOWING IRPC FILLS AN AREA OF MEMORY WITH AT MOST
;      EIGHT BYTES OF DATA:
0000 #   LEN   SET      0      ;INITIALIZE LENGTH TO 0
          IRPC    N,SHORT
          DB      '&N'
          LEN     SET      LEN+1
          IF      LEN = 8
            EXITM      ;STOP MACRO IF AREA IS FULL
          ENDIF
          ENDM
0000+53   DB      'S'
0001+48   DB      'H'
0002+4F   DB      'O'
0003+52   DB      'R'
0004+54   DB      'T'
;
;      THE FOLLOWING MACRO PERFORMS EXACTLY THE SAME FUNCTIONS AS
;      SHOWN ABOVE, BUT ABORTS EXPANSION WHEN LENGTH EXCEEDS 8
;
0000 #   LEN   SET      0      ;INITIALIZE LENGTH COUNTER
          IRPC    N, LONGSTRING
          DB      '&N'
          LEN     SET      LEN+1
          IF      LEN EQ 8
            EXITM
          ENDM
0005+4C   DB      'L'
0006+4F   DB      'O'
0007+4E   DB      'N'
0008+47   DB      'G'
0009+53   DB      'S'
000A+54   DB      'T'
000B+52   DB      'R'
000C+49   DB      'I'
000D      END

```

Listing 8-21: **Program Listing:** EXITM Example

8.5. The LOCAL Statement

It is often useful to “generate” labels for jumps or data references which are unique on each repetition of a macro. This facility is available through the LOCAL statement, which takes the form

```

macro-heading
label:  LOCAL id-1,id-2,. . .,id-n
      ENDM

```

where the label is optional, “macro-heading” is a REPT, IRPC, or IRP heading as discussed above (or a MACRO heading as discussed in following sections), and *id-1* through *id-n* represent one or more assembly language identifiers which do not contain embedded “\$” separators. The LOCAL statement must occur within the body of a macro definition. Although MAC allows the LOCAL statement to appear anywhere within the macro body, it should appear immediately following the macro header to be compatible with the standard Intel macro facility.

The action of the assembler upon encountering the LOCAL statement is to create a new name of the form

??nnnn

for association with each identifier in the LOCAL list, where *nnnn* is a four digit decimal value, assigned in ascending order starting at 0001. Whenever one of the identifiers in the list is encountered, the corresponding created name is substituted in its place. Substitution occurs according to the same rules as the controlling identifier in the IRPC and IRP groups.

The user should avoid the use of labels which begin with the two characters “??” so that no conflicting names will accidentally occur. Further, symbols which begin with “??” are not normally included in the sorted symbol list at the end of assembly (see Section 11 to override this default). Lastly, a total of 9999 LOCAL labels can be generated in any assembly, and an overflow error will occur if more generations are attempted.

Listing 8-22 shows an example of a program which uses the LOCAL statement to generate both data references and jump addresses. This program uses the CP/M disk operating system to print a series of four generated messages, as shown in the output from the program in Listing 8-23. The program begins with “equates” which define the disk system primary entry point, along with names for the non graphic ASCII characters CR and LF (carriage return and line feed). The REPT statement which follows contains a LOCAL statement with the identifiers X and Y which are used throughout the body of the REPT group. On the first iteration, X’s value becomes ??0001 which is the first generated label, while Y’s value becomes ??0002. Note that the substitution for X and Y within the generated strings follows the rules stated for controlling identifiers in previous sections. Upon completion, four messages are generated along with four CALL’s to the PRINT subroutine. At each call to PRINT, the message address is present in the DE register pair. The subroutine loads the “print string” function number into register C (C = 9) and calls the disk system to print the string value.

Upon completion of the program, control returns to the console command processor (CCP) for further operations. This particular program uses the default stack which is passed by the CCP (approximately 16 levels are available). Although this example is primarily intended to show operation of the LOCAL statement, the reader may wish to consult the *CP/M Interface Guide* to determine BDOS interface conventions in order to follow this example completely.

```

0100          ORG      100H          ;BASE OF THE TRANSIENT AREA
0005 =        BDOS    EQU      5          ;BDOS ENTRY POINT
000D =        CR      EQU      0DH        ;CARRIAGE RETURN (ASCII)
000A =        LF      EQU      0AH        ;LINE FEED (ASCII)

9. Definition and Evaluation of Stored Macros

The “stored macro” facility of MAC allows the programmer to name a sequence of assembly language “prototype” statements for selective inclusion at various places throughout the assembly process. Macro parameters can be supplied in various forms at the point of expansion which are substituted as the prototype statement are re-read. These parameters are generally used to tailor the individual macro expansion for a particular case.

Although similar in concept to subroutine definition and call, macro processing is purely textual manipulation at assembly time. That is, macro definitions causes source text to be saved in the assembler’s internal tables, and any particular expansion involves manipulation and re-reading of the saved text. These concepts will become clear as the individual macro forms are discussed.

In general, macro features can be combined in various ways to greatly enhance the facilities which are available to the programmer. Specifically, the programmer can easily manipulate generalized data definitions, macros can be defined for generalized operating systems interface, simplified program control structures can be defined and non standard instruction sets (such as the Z-80) can be supported. Finally, well designed macros for a particular application can achieve a measure of machine independence. All of these notions will be covered in the sections which follow.

9.1. The MACRO-ENDM Group

The prototype statements for a stored macro are given in the macro body enclosed by the MACRO and ENDM pseudo operations, taking the general form

```
macname    MACRO d1,d2,...,dN
             statement1
             statement2
             ...
             statementM
label:    ENDM
```

where the “*macname*” is any non conflicting assembly language identifier, *d1* through *dN* constitutes a (possibly empty) list of assembly identifiers without imbedded “\$” separators, and *statement1* through *statementM* are the macro prototype statements. The identifiers denoted by *d1* through *dN* are called “dummy parameters” for this particular macro and, although they must be unique among themselves, can generally be identical to any program identifiers outside the macro body without causing a conflict. The prototype statements may contain any properly balanced assembly language statements or groups, including nested REPT’s, IRP’s, IRPC’s, MACRO’s and IF’s.

The prototype statements are read and stored in the assembler's internal tables under the name given by "*macname*", but are not processed until the macro is expanded. The expansion process is given in the following section.

As before, the *label* preceding the `ENDM` is optional.

9.2. Macro Invocation

The macro text which is stored through a `MACRO`-`ENDM` group can be brought out for processing through a statement of the form

label: macname a1,a2, ..., aN

where the *label* is optional, and *macname* has previously occurred as the identifier on a `MACRO` heading. The "actual parameters" *a1* through *aN* are sequences of characters, separated by commas and terminated by a comment or end-of-line.

Upon recognition of the *macname*, the assembler first "pairs-off" each dummy parameter in the `MACRO` heading (*d1* through *dN*) with the actual parameter text (*a1* through *aN*) by associating the first dummy parameter with the first actual parameter (*d1* is paired with *a1*), the second dummy is associated with the second actual, and so forth until the list is exhausted. If more actual's are provided than dummy parameters then the extras are ignored. If fewer actual's are provided then the extra dummy parameters are associated with the empty string (i.e., a text string of zero length). It is important to realize at this point that the value of a dummy parameter is not a numeric value, but is instead a textual value consisting of a sequence of zero or more ASCII characters.

After each dummy parameter is assigned an actual textual value, the assembler re-reads and processes the previously stored prototype statements and substitutes each occurrence of a dummy parameter by its associated actual textual value, according to the same rules as the controlling identifier in an `IRPC` or `IRP` group.

Listing 9-24 and Listing 9-25 provide examples of macro definitions and invocations.

Listing 9-24 begins with the definition of three macros, called `SAVE`, `RESTORE`, and `WCHAR`. The `SAVE` macro contains prototype statements which save the principal CPU registers (`PUSH PSW, B, D, and H`), while the `RESTORE` macro restores the principal registers (`POP H, D, B, and PSW`). The `WCHAR` macro contains the statements necessary to write a single character at the console using a CP/M BDOS call.

Note that the occurrence of the `SAVE` macro definition between `MACRO` and `ENDM` causes the assembler to read and save the `PUSH`'s, but does not assemble the statements into the program. Similarly, the statements between the `RESTORE` `MACRO` and corresponding `ENDM` are saved, as are the statements between the `WCHAR` `MACRO` and `ENDM` group. The fact that the assembler is reading

the macro definition is indicated by the blank columns in the leftmost 16 columns of the output listing.

Referring to Listing 9-24, note that machine code generation starts following the invocation of the `SAVE` macro. The prototype statements which were previously stored are re-read and assembled, with a “+” between the machine code address and the generated code to indicate that the statements are being recalled and assembled from a macro definition. Note that the `SAVE` macro has no dummy parameters in the definition and thus there are no actual parameters required at the point of invocation.

The invocation of `SAVE` is immediately followed by an expansion of the `WCHAR` macro. The `WCHAR` macro, however, has one dummy parameter, called `CHR`, which is listed in the macro definition header. This dummy parameter represents the character to pass to the BDOS for printing. In the first expansion of the `WCHAR` macro, the actual parameter “H” becomes the textual value of the dummy parameter `CHR`. Thus, the `WCHAR` macro expands with a substitution of the dummy parameter `CHR` by the value `H`. Note that the use of `CHR` is within string quotes and thus must be typed in upper case and preceded by the ampersand operator. Following the reference to `WCHAR`, the prototype statements are listed with the “+” sign to indicate that they are generated by the macro expansion.

The second invocation of `WCHAR` is similar to the first except that the dummy parameter `CHR` is assigned the textual value `I`, causing generation of a `MVI E, 'I'` for this case.

After the listing of the second `WCHAR` expansion, the `RESTORE` macro is invoked, causing generation of the `POP` statement to restore the register state. The `RESTORE` is followed by a `RET` to return to the CCP following the character output.

This particular program thus performs the simple function of saving the registers upon entry, typing the two characters “HI” at the console, restoring the registers, and then returns to the Console Command Processor. One should note that the `SAVE` and `RESTORE` macros are used here for illustration, and are not required for interface to the CCP since all registers are assumed invalid upon return from a user program. Further, this program uses the CCP’s stack throughout, which is only eight levels deep.

Listing 9-24: **Assembly Listing:** Example of Macro Definition and Invocation

Listing 9-25 shows another macro for printing at the console. In this case, the PRINT macro uses the operating system call which prints the entire message starting at a particular address until the “\$” symbol is encountered. The PRINT macro has a slightly more complicated structure: two dummy parameters must be supplied in the invocation. The first parameter, called N, is a count of the number of carriage-return line-feeds to send after the message is printed. The second parameter, called MESSAGE, is the ASCII string to print which must be passed as a quoted string in the invocation. The LOCAL statement within the macro generates two labels denoted by PASTM and MSG. When the macro expands, substitutions will occur for the two dummy parameters by their associated actual textual values, and for PASTM and MSG by their sequentially generated label values. The macro definition contains prototype statements which branch past the message (to PASTM) which is included inline following the label MSG. The message is padded with N pairs of carriage-return line-feed sequences, followed by the “\$” which marks the end of the message. The string address is then sent to the BDOS for printing at the console.

There are two invocations of the PRINT macro included in Listing 9-25. The invocation sends two actual parameters: the textual value 2 is associated with the dummy N, followed by a quoted string which is associated with the dummy parameter MSG. Note that the second actual parameter includes the string quotes as a part of the textual value. Note also that the generated message is preceded by a jump instruction, and followed by N = 2 carriage-return line-feed pairs.

The second invocation of the PRINT macro is similar to the first, except that the REPT group is executed N = 0 times, resulting in no generations of the carriage return line-feed pairs.

Similar to Listing 9-24, the program of Listing 9-25 uses the Console Command Processor's eight level stack for the BDOS calls. When the program executes, it types the two messages, separated by two lines, and returns to the CCP.

Listing 9-25: **Assembly Listing:** Sample Message Print-out Macro

9.3. Testing Empty Parameters

Before continuing the discussion of macro definition and invocation, it is necessary to discuss a particular operator, called the NUL operator, which is specifically designed to allowing testing of null parameters (i.e., actual parameters of length zero). The

NUL operator is used in an expression as a unary operator, and produces a true value if its argument is of length zero and a false value if the argument has length greater than zero. Thus, the operator appears in the context of an arithmetic expression as:

... NUL *argument*

where the ellipses represent an optional prefixing arithmetic expression, and “argument” is the operand used in the NUL test. Note that the NUL differs from other operators since it must appear as the last operator in the expression. This is due to the fact that the NUL operator “absorbs” all remaining characters in the expression until the following comment or end of line is found. Thus, the expression

X GT Y AND NUL XXX

is valid since NUL absorbs the argument XXX (producing a false value) in the scan for the end of line. The expression

X GT Y AND NUL

is also valid, however, since the argument following the NUL is empty, thus causing NUL to return a true value since the end of line is immediately encountered in the scan. Intervening blanks and tabs are ignored in this scanning process. The expression

X GT Y AND NUL M + Z)

is somewhat deceiving, but nevertheless valid even though it appears as if it is an unbalanced expression. In this case, the argument following the NUL operator is the entire sequence of characters “M + Z)” which is absorbed by the NUL operator in scanning for the end of line. The value of “NUL M + Z)” is “false” since the sequence is not empty.

Listing 9-26 gives several examples of the use of NUL in a particular program. In the first case, NUL returns true since there is an empty argument following the operator. Thus, the “true case” is assembled (as indicated by the machine code to the left), and the “false case” is ignored. Similarly, the second use of NUL in Listing 9-26 produces a false value since the argument is non-empty. Both uses of NUL, however, are contrived examples, since NUL is really only useful within a macro group, as shown in the definition of the NULMAC macro.

```

0000 7472756520      IF      NUL
                      DB      'true case'
                      ELSE
                      DB      'false case'
                      ENDIF
;
                      IF      NUL XXX
                      DB      'xxx is nul'
                      ELSE

00A8                  END

```

Listing 9-26: **Sample Program:** using the NUL Operator

NULMAC consists of a sequence of three conditional tests which demonstrate the use of NUL in checking empty parameters. In each of the tests, a “DB” is assembled if the argument is not empty, and skipped otherwise. Six invocations of NULMAC follow its definition, giving various combinations of empty and non-empty actual parameters.

In the first case, NULMAC has no actual parameters and thus all dummy parameters (A, B, and C) are assigned the empty sequence. As a result, all three conditional tests produce false results since both A and B are empty, and B&C concatenates two empty sequences, producing an empty sequence as a result.

The second invocation of NULMAC provides only one actual parameter (xxx) which is assigned to the dummy parameter A, while B and C are both assigned the empty sequence. Thus, only the “DB” for the first conditional test is assembled.

The third case is similar to the second, except that the actual parameters for A and C are omitted. Thus, the second and third conditionals both test “NOT NUL XXX” which is true since B has the value xxx, and B&C produces the value xxx as well.

The fourth invocation of `NULMAC` skips the actual parameter for `B`, but supplies values for both `A` and `C`. Thus, the first and third test result in true values, while the second conditional group is skipped.

The fifth invocation provides an actual parameter only for `C`. As a result, only the third conditional is true, since `B&C` produces the sequence `YYY`.

The sixth invocation produces exactly the same result as the first, since all three actual parameters are empty.

The final expansion of `NULMAC` in Listing 9-26 shows a special case of the `NUL` operator. The expression

```
NUL ' '
```

(where the two apostrophes are in juxtaposition) produces the value `true` even though there are two apostrophe symbols on the line following `NUL` and before the end of line. Note that the value of `A` is the empty string in this case, while the value assigned to both `B` and `C` consists of the two apostrophe characters side-by-side, which is treated as a quoted string of length zero (even though it is a sequence of two characters!). In this last expansion, the first conditional produces a false value since `A` is associated with the empty sequence. The second conditional, however, evaluates the form

```
NOT NUL ' '
```

which is the special case of `NUL` applied to a length zero quoted string (not a length zero sequence, however). Because of the special treatment of the length zero quoted string, this expression also produces a false result. The third conditional, however, must be considered carefully: the original expression in the macro definition takes the form

```
NOT NUL B&C
```

with `B` and `C` both associated with the sequence of length two given by two adjacent apostrophes. Thus, the macro assembler examines

```
NOT NUL ' '&' '
```

or, after concatenation,

```
NOT NUL ' '' '
```

where the four apostrophes are juxtaposed. Considering only the four adjacent apostrophes, the macro assembler considers this a quoted string which happens to contain a single apostrophe, since double apostrophes within strings are always reduced to a single apostrophe. As a result, the test produces a true value and the conditional segment is assembled. If this all seems confusing, that's because it is. Fortunately, these cases are very specialized, and are included here for completeness. Under normal circumstances, the `NUL` operator is used only to test for missing arguments, as shown in later examples (see Listing 9-29 for a particular case).

9.4. Nested Macro Definitions

The MAC assembler allows the programmer to include nested macro definitions, which take the form

```
mac1      MACRO mac1-list
mac2      MACRO mac2-list
...
ENDM
ENDM
```

where “*mac1*” is the identifier corresponding to the outer macro, and “*mac2*” is an identifier corresponding to an inner nested macro which is wholly contained within the outer macro. In this case, “*mac1-list*” and “*mac2-list*” correspond to the dummy parameter lists for *mac1* and *mac2*, respectively. As before, *labels* are allowed on the ENDM statements.

Recall that the statements contained within a macro definition are “prototype” statements which are read and stored by the assembler, but not evaluated as assembly language statements until the macro is expanded. Thus, in the form shown above, only the *mac1* macro can be available for expansion, since the assembler has stored but not processed the body of *mac1* which contains the definition of *mac2*. That is, *mac2* cannot be expanded until *mac1* is first expanded revealing the definition of *mac2*.

Properly balanced imbedded macros of this form can be nested to any level, but cannot be referenced until their encompassing macros have themselves been expanded.

Listing 9-27 gives a practical example of nested macro definition and expansion. This particular program writes characters to either the CP/M console device or the currently assigned list device, according to the value of the LISTDEV flag which is set for the assembly. If the LISTDEV flag is true, then the assembly sends characters to the listing device, otherwise the console is used for output. In either case, the macro OUTPUT is produced which sends a single character to whatever device is selected.

```

0100          ORG      100H      ;BASE OF THE TPA

Listing 9-27: **Sample Program:** using a Nested Macro Definition

For purposes of illustration, the macro SETIO is used to construct the OUTPUT macro. Note in Listing 9-27 that the OUTPUT macro is wholly contained within the SETIO macro and, as a result, remains undefined until SETIO expands. Upon encountering the invocation of SETIO, the macro assembler reads the prototype statements within SETIO and, in the process, constructs the definition of the OUTPUT macro. Since LISTDEV is true for this assembly, the OUTPUT macro becomes defined as

```

OUTPUT  MACRO CHAR
        MVI  E,CHAR
        MVI  C,LISTOUT
        CALL BDOS
        ENDM

```

Note that the SETIO macro itself uses this newly created OUTPUT macro in its last prototype statement to print a single "*" at the selected device.

Following the invocation of SETIO, the invocations of OUTPUT are recognized since its definition has been entered in the process of reading the prototype statements of SETIO. These invocations send the characters "1" and "2" to the list device, respectively.

9.5. Redefinition of Macros

It is often useful to redefine the prototype statements of a particular macro after the initial prototype statements have been entered. This is often simply a particular case of the previous section, where the inner nested macro carries the same name as the encompassing macro definition. Although this feature may seem somewhat frivolous, there is one particular case where macro redefinition is extremely useful: if the macro uses a subroutine then the subroutine can be included on the first expansion and simply called in any remaining expansions. Thus, if the macro is never invoked then the subroutine is not included in the program.

Listing 9-28 shows an example of macro redefinition. In this case, the macro `MOVE` is defined which is intended to move byte values from a starting “source address” to a target “destination address” for a particular number of bytes. The three dummy parameters denote these three values: `SOURCE` is the starting address, `DEST` is the destination address, and `COUNT` is the number of bytes to move (a constant in the range 0-65535). The actions of the `MOVE` macro, however, are sufficiently complicated that they should be performed through a subroutine, rather than inline machine code each time `MOVE` is expanded.

```
0100      ORG      100H          ;BASE OF TPA
      MOVE     MACRO  SOURCE,DEST,COUNT
      ;;      MOVE DATA FROM ADDRESS GIVEN BY 'SOURCE'
      ;;      TO ADDRESS GIVEN BY 'DEST' FOR 'COUNT' BYTES
      LOCAL   PASTSUB ;;LABEL AT END OF SUBROUTINE
      ;;
      JMP     PASTSUB ;;JUMP AROUND INLINE SUBROUTINE
@MOVE:  ;;INLINE SUBROUTINE TO PERFORM MOVE OPERATION
      ;;      HL IS SOURCE, DE IS DEST, BC IS COUNT
      MOV     A,C      ;;LOW ORDER COUNT
      ORA     B        ;;ZERO COUNT?
      RZ      ;;STOP MOVE IF ZERO REMAINDER
      MOV     A,M      ;;GET NEXT SOURCE CHARACTER
      STAX    D        ;;PUT NEXT DEST CHARACTER
      INX     H        ;;ADDRESS FOLLOWING SOURCE
      INX     D        ;;ADDRESS FOLLOWING DEST
      DCX     B        ;;COUNT=COUNT-1
      JMP     @MOVE    ;;FOR ANOTHER BYTE TO MOVE
PASTSUB:

014C             END

```

Listing 9-28: **Sample Program:** using Macro Redefinition

Examining the structure of MOVE in Listing 9-28, note that it contains a properly nested redefinition of MOVE, taking the general form:

```

MOVE  MACRO  SOURCE, DEST, COUNT
@MOVE subroutine
MOVE  MACRO ?S,?D,?C
    call to @MOVE
    ENDM
    invocation of MOVE
    ENDM

```

The action of the assembler upon encountering the first invocation of MOVE is to begin reading the prototype statements. Note, however, that the first expansion of the MOVE includes the subroutine for the actual move operation, labelled by @MOVE so that there is no name conflict (with a branch around the subroutine). MOVE then redefines itself as a sequence of statements which simply call the out-of-line subroutine each time it expands. In fact, the last statement of the original MOVE macro is an invocation of the newly defined version. As indicated by this example, once a macro has started expansion, it will continue to completion (or until EXITM is assembled), even if it redefines itself.

It is important to note the use of ?S, ?D, and ?C in the above example. The innermost MOVE macro uses the same sequence of three parameters for the source, destination, and count. The dummy parameter names must differ, however, since they would be substituted by their actual values if they were the same. This is due to the fact that the inner MOVE macro is wholly contained within the outer macro and thus parameter substitution takes place irregardless of the context.

Macro storage is not reclaimed upon redefinition, however, since the macro assembler performs two passes through the source program and saves any preceding definitions for the second pass scan.

9.6. Recursive Macro Invocation

A “recursive” macro *x* has the property that its prototype statements contain invocations of macros which, in turn, invoke macros which eventually lead back to an invocation of *x*. A particular case of recursion, called “direct recursion,” occurs when *x* invokes itself, as shown in the form below:

```
macname      MACRO d1, d2, ..., dN
               ...
               macname a1, ..., aN
               ...
            ENDM
```

Although this form is similar to the embedded macro definition discussed in the previous section, note that “*macname*” is being expanded within its own definition, rather than being redefined. Recursion is only useful, however, in the presence of conditional assembly where various tests are made which prevent infinite recursion. In fact, recursion is only allowed to sixteen levels before returning to complete the expansion of an earlier level.

Listing 9-29 shows a situation where (indirect) recursive macro invocation is useful. The macro `WCHAR` writes a character to the console device using the general-purpose operating system macro `CBDOS` (call `BDOS`). `CBDOS` acts as an interface between the program and the CP/M system by performing the system function given by `FUNC`, with optional “information address” `INFO`. In particular, `CBDOS` loads the specified function to register `C`, then tests to see if the `INFO` argument has been supplied (using the `NUL` operator). If supplied, `INFO` is loaded to the `DE` register pair. After register setup, the `BDOS` is called, and the macro has completed its expansion.

```

```

Listing 9-29: **Sample Program:** using a Recursive Macro

Assume, however, that CBDOS has the additional task of inserting a carriage return line-feed before writing messages in the particular case that operating system function 9 (write buffer until "\$") has been specified. In this case, CBDOS uses the WCHAR macro to send the carriage-return line-feed. Note, however, that the WCHAR macro, in turn, uses CBDOS to send the character resulting in two activations of CBDOS at the same time. The assembler holds the initial invocation of CBDOS until the WCHAR macro has completed, then returns to complete the initial CBDOS expansion.

An important observation in the presence of recursion is that the values of the dummy parameters are saved at each successive level of recursion, and restored when that level of

recursion is re-instated. In particular, re-entry into a macro expansion through recursion does not destroy the values of dummy arguments held by previous entry levels.

9.7. Parameter Evaluation Conventions

There are a number of options which the programmer can exercise in the construction of actual parameters, as well as in the specification of character-lists for the `IRP` group. Although an actual parameter is simply a sequence of characters placed between parameter delimiters, these options allow overrides where delimiter characters themselves to become a part of the text. In general, a parameter `x` occurs in the context:

label: macname < ..., `x`, ... >

where “*macname*” is the name of a previously defined macro, and the preceding *label* is optional. The ellipses “...” represent optional surrounding actual parameters in the invocation of *macname*. In the case of an `IRP` group, the occurrence of a character-list `x` would be

label: IRP id, ..., `x`, ...

where the *label* is again optional, and the ellipses represent optional surrounding character-lists for substitution within the `IRP` group where the controlling identifier “*id*” is found. In either case, the statements could be contained within the scope of a surrounding macro expansion. Hence, dummy parameter substitution could take place for the encompassing macro while the actual parameter is being scanned.

The macro assembler follows the steps shown below in forming an actual parameter or character-list:

- (a) leading blanks and tabs (CTRL-I) are removed if they occur in front of `x`. After this “deblanking” has occurred,
- (b) the leading character of `x` is examined to determine the type of scan operation which is to take place;
- (c) if the leading character is a string quote (apostrophe), then `x` becomes the text up through and including the balancing string quote, using the normal string scanning rules: double apostrophes within the string are reduced to a single apostrophe, and upper case dummy parameters adjacent to the ampersand symbol are substituted by their actual parameter values. Note that the string quotes on either end of the string are included in the actual parameter text.
- (d) If instead the first character is the left broken bracket “<” then the bracket is removed, and the value of `x` becomes the sequence of characters up to, but not including, the balancing right broken bracket “>” which does not become a part of `x`. In this case, left and right broken brackets may be nested to any level within `x`, and only the outer brackets are removed in the evaluation. Quoted strings within the brackets are allowed, and substitution

within these strings follows the rules stated in (c) above. Note that left and right brackets within quoted strings become a part of the string, and are not counted in the bracket nesting within *x*. Further, the delimiter characters comma, blank, semicolon, tab, and exclaim become a part of *x* when they occur within the bracket nesting.

- (e) If the leading character is a percent “%”, then the sequence of characters which follows is taken as an expression which is evaluated immediately as a 16-bit value. The resulting value is converted to a decimal number and treated as an ASCII sequence of digits, with left zero suppression (0-65535).
- (f) If the leading character is neither a quote nor a left bracket nor a percent, the (possibly empty) sequence of characters which follow, up to the next comma, blank, tab, semicolon, or exclaim symbol, becomes the value of *x*.

There is one important exception to the above rules: the single character escape, denoted by an up-arrow, causes the macro assembler to read the immediately following special (non alphabetic) character as a part of *x* without treating the character as significant. The character which follows the up-arrow, however, must be a blank, tab, or visible ASCII character. The up-arrow itself can be represented by two up arrows in succession. If the up-arrow directly precedes a dummy parameter, then the up-arrow is removed and the dummy parameter is not replaced by its actual parameter value. Thus, the up-arrow can be used to prevent evaluation of dummy parameters within the macro body. Note that the up-arrow has no special significance within string quotes, and is simply included as a part of the string.

Evaluation of dummy parameters in macro expansions must also be considered, although this topic has been presented throughout the previous sections. Generally, the macro assembler evaluates dummy parameters as follows:

- (a) If a dummy parameter is either preceded or followed by the concatenation operator “&”, then the preceding and/or following “&” operator is removed, the actual parameter is substituted for the dummy parameter, and the implied delimiter is removed at the position(s) the ampersand occurs.
- (b) Dummy parameters are replaced only once at each occurrence as the encompassing macro expands. This prevents the “infinite substitution” which would occur if a dummy parameter evaluated to itself.

In summary, parameter evaluation follows these rules:

- leading and trailing tabs and blanks are removed
- quoted strings are passed with their string quotes intact
- nested brackets enclose arbitrary characters with delimiters
- a leading percent symbol causes immediate numeric evaluation

- an up-arrow passes a special character as a literal value
- an up-arrow prevents evaluation of a dummy parameter
- the “&” operator is removed next to a dummy parameter
- dummy parameters are replaced only once at each occurrence

Listing 9-30, Listing 9-31, and Listing 9-32 show examples of macro definitions and invocations which illustrate these points. In Listing 9-30, for example, two macros are defined, called MAC1 and MAC2, which each have several dummy parameters. In this case, the macro definitions are headed by “DB” statements in order to reveal the actual values which are passed in each case. There is a single (mainline) invocation of MAC1 with the actual parameters

```
I , , X+1, % X + 1, 'kwote'
```

which associates I with E, the null sequence with F, the sequence X+1 with G, the value 16 with H, and the literal string 'kwote' with S. MAC2 expands, filling the DB and MVI instructions with the substituted values. Before leaving MAC2, MAC1 is invoked with the value of E (the sequence I), the concatenation of the dummy argument F with the sequence M (producing “M” since F’s value is null), along with the literal value A, followed by the value of H (which is 16), and terminated by the value of S (yielding the string 'kwote'). These values are associated with MAC1’s dummy parameters. Upon expanding MAC1, the DB statements are filled-out, followed by the substitution of A as a label (producing A’s value 1). The MVI instruction references memory since B’s value is M. Note that the concatenation of C with 1 reduces to a concatenation of A with 1 since C’s value is A. The replacement of C by A constitutes a substitution of a single occurrence of a dummy parameter, and thus the A which is produced is not itself replaced at this point. Finally, the literal value L is concatenated to the value of A and D to produce the label LI16.

```

Listing 9-30: **Assembly Listing:** Macro Parameter Evaluation Example

Listing 9-31 illustrates the use of bracketed notation, using IRP's (indefinite repeats) within two macros, called IRPM1, IRPM2, and IRPM3. Note that one bracket level is removed in the first invocation of IRPM1, leaving the IRP list with one bracket level (required in the IRP heading). Similarly, the IRPM2 invocation also eliminates the outer bracket level, but these brackets are replaced at the IRP heading within IRPM2. IRPM3 has three distinct dummy parameters which are reconstructed as a single list at the IRP heading which it contains. IRPM4 shows the effect of passing parameters through two macro invocation levels by accepting a single parameter X, which is immediately passed along to the IRPM1 macro. Note that the invocation requires three bracket levels: the first is removed at the invocation of IRPM4, the second level is removed at the nested invocation of IRPM1 inside IRPM4, and the innermost level is required at the IRP heading within IRPM1.

	IRPM1	MACRO	X

000C		END	

Listing 9-31: **Assembly Listing:** Parameter Evaluation using Bracketed Notation

Listing 9-32 presents various combinations of bracketed actual parameters, quoted strings, and escape sequences. The MAC1 macro has two parts: the first portion includes a “DB” statement which shows the value of the first parameter x (if it is not empty), and the second part produces the value of y, if not empty. Note that the first invocation includes a properly nested bracketed sequence for x, and an empty parameter for y. The second invocation sends a properly nested bracketed expression for x which produces an empty value since no characters remain after the brackets are removed. The second parameter includes a quoted string (‘string of pearls’) and a hexadecimal value which becomes a part of the “DB” in MAC1.

The third invocation of MAC1 passes a bracketed expression, which includes a quoted string (i.e., the pair of adjacent apostrophes), followed immediately by a sequence of ASCII characters. Note that the pair of apostrophes are passed intact since they appear as an empty quoted string. In this case, the value of y is empty. The remaining examples show various cases of strings and escape sequences. In particular, one must take care in passing quoted strings which themselves contain apostrophes, since a pair of apostrophes is considered a single apostrophe at each

evaluation level in the sequence of macro invocations. Pay particular attention to the use of the escape character to pass an unevaluated dummy parameter from MAC2 to the MAC1 invocation. It is worthwhile examining the various parameters and their evaluations in Listing 9-32 to ensure that the rules for evaluation given in this section are consistent.

Listing 9-32: **Assembly Listing:** Examples of Macro Parameter Evaluation

9.8. The MACLIB Statement

The macro assembler allows the programmer to create and reference “macro library” files which are external to the mainline program. The form of the macro library reference is

MACLIB *libname*

where “*libname*” is an identifier which references a particular file “*libname*.LIB” which is assumed to exist on the diskette. Macro libraries are in source program form, and can thus be easily created and modified by the programmer using the CP/M system editor (ED).

In order to speed-up the assembly process, macro libraries are read only on the first assembly pass. This places some restrictions on the use of the MACLIB statement, as listed below:

- (a) the statements included in the macro library cannot generate machine code. For example, comments, EQU's, SET's, and MACRO definitions are allowed, while DB statements outside macro definitions are not allowed.
- (b) Macro libraries are not normally listed with the source program (although there is an overriding parameter which can be supplied - see Section 11).
- (c) All MACLIB statements must appear before the mainline program macro definitions.
Generally, the MACLIB statements are placed at the beginning of the program, followed by the mainline declarations and machine code.

The principal advantage of the MACLIB feature is that the programmer can predefine macros which enhance the facilities of the assembly language itself. For example, the additional operations codes of the Zilog Z-80 microprocessor can be defined in a macro library which is reference in a single statement

```
MACLIB  Z80
```

which causes the assembler to read the file "Z80.LIB" from the diskette, containing the necessary macros for Z-80 code generation. These macros can then be referenced within the program intermixed with the usual 8080 mnemonics.

Normally, the "*libname*.LIB" file is assumed to exist on the currently logged disk drive. The programmer can override this default condition using a special parameter (L) when the macro assembler is started which redirects the ".LIB" references to a different diskette (see Section 11).

Listing 7-15 and Listing 7-16 show the use of the macro library facility, as introduced in the initial macro discussion. The following sections contain additional examples of the use of MACLIB in practical applications.

10. Applications of Macros

The MAC assembler provides a powerful tool for microcomputer systems development through its macro facilities. In order to demonstrate this tool, a number of applications of macros in the solution of practical problems are described in some detail in the following sections. Four particular applications areas are considered: use of macros in implementation of special-purpose languages, emulation of non-standard machine architectures, implementation of additional control structures, and operating systems interface macros.

10.1. Special Purpose Languages

A wide variety of microcomputer designs can be broadly classed as “controller” applications. Specifically, the microcomputer is used as the controlling element in sequencing and decision-making as real-time events are sampled and directed.

Typical applications of this sort include assembly line sensing and control, metal machine control, data communications and terminal control functions, production instrumentation and testing, and traffic control systems.

In many cases, application programmers set up the sequence of operations that the microprocessor is to carry-out in performing its particular task. In order to avoid unnecessary details, the application programmer is not expected to know how to program and debug microcomputer assembly language programs.

In this situation, it is useful to define a “language” through macros which suits the particular application. The application programmer then uses these predefined macros as the primitive language elements. If properly defined, the application language is easily programmed, allowing considerable machine independence. That is, an application program written for a particular microprocessor can be used with another processor by changing the definitions of the individual macros which implement the primitive operations. Further, the macro bodies can incorporate debugging facilities for application development.

In order to illustrate the notion of language definition, consider the following situation.

Hornblower Highway Systems, Inc., produces “turnkey” traffic control systems for cities throughout the country. Their hardware subsystems consist of various traffic lights and sensors which are customized for the traffic layout in a particular city. When *Hornblower* negotiates a contract, their engineers survey the intersections of the city, and produce plans which show a configuration of their standard hardware for each intersection, along with the “algorithms” required for traffic flow at that point.

The standard hardware items which *Hornblower* manufactures consist of the following. Central and corner traffic lights which display green, yellow, and red (or off completely), pushbutton

switches for pedestrian cross requests, road “treadles” for sensing the presence of an automobile at an intersection, and a central controller box.

The central controller box contains an 8080 microcomputer connected through external logic to relays which control the lights, and “latches” which holds the sensor input information. The controller box also contains a time of day clock, which changes on an hourly basis from 0 through 23. The 8080 processor in the controller box can be configured for any particular intersection with up to 1024 bytes of programmable read only memory (PROM) in 256 byte increments. Although random access memory can be included in the controller box, *Hornblower* uses only ROM when possible.

Thus, the *Hornblower* engineers examine the hardware requirements for each intersection in the city, and produce a set of hardware configuration plans which intermix the various standard components. Programs are then written and debugged which control each intersection, based upon predicted traffic patterns.

The intersection of Easy St. and Maria Ave., for example, controls minimal traffic and thus consists of a controller box with a single central light. The “algorithm” for this intersection is to simply alternate red and green lights between Easy and Maria, with a “bias” toward Easy St., since traffic along Easy has measured higher in the past surveys. Thus, the green light along Easy lasts for 20 seconds, while the green along Maria last only 15 seconds. Given this situation, the application programmer writes the following program:

The macro library “INTERSECT.LIB” contains the macro definitions which implement the “primitive” operations SETLITE and TIMER which set the central traffic light, and time-out for the specified interval, respectively. Further, the RETRY macro causes the traffic light to recycle on each light change. Note that the sequence of operations is easy to write, and is completely machine independent.

Listing 10-33 gives an example of a macro library for “intersect” which assumes the following hardware with an 8080 processor: the central traffic light is controlled by the 8080 output port 0 (given by “light”), while the time of day clock is read from port 3 (“clock”). Further, the north-south (“nsbits”) of the central light are given by the high order 4 bits of output port 0, while the east-west direction (“ewbits”) is specified in the low order 4 bits of output port 0. When either of these fields is set to 09 19 2, or 3, the light in that direction is turned off, or set to red, yellow, or green, respectively. Thus, the SETLITE macro in Listing 10-33 accepts both a direction (NS or EW), along with a color (OFF, RED, YELLOW, or GREEN), and sets the specified direction to the appropriate color.

```

;      macro library for basic intersection
;

Listing 10-33: **Program Source:** Macro Library for Basic Intersection

The `TIMER` macro in Listing 10-33 uses the internal cycle time of the 8080 processor to construct an inline timing loop, based on the value of `SECONDS`. Note that this loop is not generated as a subroutine, since *Hornblower* prefers not to include RAM in the controller box (subroutines require return addresses in RAM).

In addition to the basic intersection macro library, *Hornblower* has also defined macro libraries for all of the optional hardware components. Listing 10-34, for example, is included when the intersection contains treadles in the street to detect automobiles, while Listing 10-35 shows the macro library for pedestrian push-buttons. In the case of automotive treadles, the sensors are attached to input port 1 (“`trinp`”) of the processor. The treadles, however, require a “reset” operation which clears the latched value through output port 1 (“`trout`”) of the controlling 8080 processor. In any particular intersection, the treadles are numbered clockwise from true north, labelled 0, 1, through a maximum of 7 treadles. Each sensor and reset position of the treadle ports correspond to one bit position, numbered from the least to most significant bit. Thus the treadle #0 sensor is read from bit 0 of port 1, and reset by setting bit 0 of output port 1. Similarly, treadle #1 uses bit position 1 of input and output port 1. The `TREAD?` macro is invoked to sense the presence of a latched value for treadle “`tr`” and, if on, the sensor is reset with control transferring to the label given by “`iftrue`”

```

;      macro library for street treadles
;
trinp  equ    01h    ;treadle input port
trout  equ    01h    ;treadle output port
;
tread? macro  tr,iftrue
;;      "tread?" is invoked to check if
;;      treadle given by tr has been sensed.
;;      if so, the latch is cleared and control
;;      transfers to the label "iftrue"
local    iffalse ;;in case not set
;;
in      trinp    ;;read treadle switches
ani     1 shl tr    ;;mask proper bit
jz      iffalse ;;skip reset if 0
mvi     a,1 shl tr    ;;to reset the bit
out     trout    ;;clear it
jmp     iftrue    ;;go to true label
iffalse:
endm

```

Listing 10-34: **Program Source:** Macro Library for “treadle” Control

Listing 10-35 shows the macro library which processes pedestrian push-buttons. *Hornblower*’s hardware is set up to sense the latched pedestrian switches on input port 0 (“`ewinp`”) as a sequence 1’s and 0’s in the least significant positions, corresponding to the switches at the

intersection. Thus, if there are four pedestrian switches, bit positions 0,1,2, and 3 correspond to these switches. A “1” bit in any of these positions indicates that the pushbutton has been depressed. Unlike the automotive treadles, the crosswalk switch latches are all cleared whenever input port 0 is read. In addition to these macro libraries, *Hornblower* has defined several additional libraries which support optional hardware manufactured by their company.

```

;      macro library for pedestrian pushbuttons
;
cwinp  equ    00h      ;input port for crosswalk
;
push?  macro    iftrue
;;      "push?" jumps to label "iftrue" when any one
;;      of the crosswalk switches is depressed. The
;;      value has been latched, and reading the port
;;      clears the latched values
;      in      cwinp    ;;read the crosswalk switches
;      ani      (1 shl cwcnt) - 1      ;;build mask
;      jnz      iftrue  ;;any switches set?
;;continue on false condition
;      endm

```

Listing 10-35: **Program Source:** Macro Library for Corner Pushbuttons

The intersection of Bumpenram Boulevard and Lullabye Lane presents a somewhat more complicated situation. Bumpenram Blvd. carries heavy traffic in an E-W direction to and from the center of town. Lullabye Ln., however, feeds a residential portion of the city, running perpendicular to Bumpenram in a N-S direction. The contracting city has specified that the traffic control should be biased toward Bumpenram Blvd. as follows: the traffic light must remain green along Bumpenram until the treadles along Lullabye detect the presence of automobiles or until the pedestrian switches are pushed. At that time, the light must change to allow the traffic to move N-S through Lullabye Ln., allowing all traffic to clear before returning to the major E-W flow along Bumpenram Blvd. Late night traffic along Bumpenram is not very heavy, so the city has also specified that the E-W light flashes yellow and the N-S direction flashes red between the hours of 2 and 5 AM.

The application program created by Hornblower for the Bumpenram Blvd. and Lullabye Ln. intersection is shown in Listing 10-36. Each major cycle of the traffic light enters at “CYCLE” where the time of day is tested. If between 2 and 5, then control transfers to “NIGHT” where the yellow/red lights are flashed in the appropriate directions. If not between 2 and 5 AM, the switches and treadles are sampled until N-S traffic along Lullabye Ln. is sensed. If cross traffic is detected, the lights switch until all the traffic is through. Sampling also stops if the time of day ever reaches 2 AM.

Listing 10-36 shows the assembly with no macro generated lines (controlled by the “M” parameter - see Section 11). Although the machine code locations are shown to the left, no 8080 machine code is listed. Listing 10-37 shows a segment of this same program with machine code generation, but no 8080 mnemonics (controlled by “*M”), while Listing 10-38 shows another segment with normal macro generation. Note that Listing 10-36 is the most readable to the application programmer, while Listing 10-37 and Listing 10-38 would be useful for macro debugging.

Listing 10-38: **Assembly Listing:** Algorithm with Generated Instructions (partial)

It should be noted that the resulting program requires no random access memory for execution, since all temporary values are maintained in the 8080 registers. Further, no subroutine calls take place and thus the 8080 stack is not used. Finally, the program is less than 256 bytes, so it can be placed in a single programmable read only memory chip for a minimum memory/processor configuration.

Macro based languages of this sort can easily incorporate debugging facilities. In the case of *Hornblower, Inc.*, the principal algorithms are constructed and tested in the CP/M environment by including debugging traces within each macro. In each case, a debug “flag” is tested and, if true, machine code is generated to trace the operation at the console, rather than actually executing the input/output calls. Listing 10-39 shows the modification required to the “INTER.LIB” file to include the debugging code. Although only the SETLITE macro is shown,

similar coding is easily included for the remaining macros. Listing 10-39 includes the `debug` flag at the beginning of the library (initially set `FALSE`), along with the appropriate equates for CP/M system calls. If the `debug` flag is set to true by the application programmer, special trace calls are included. Note, for example, that the `SETLITE` macro constructs a message of the form

DIR changing to *COLOR*

where “*DIR*” and “*COLOR*” are the parameters sent to the macro. If `debug` remains false in the application program, this trace code is not assembled.

```

;      macro library for basic intersection

      endm
;
;      (remaining macros are identical to the previous figure,
;      but each contains trace information similar to "setlite")
;

```

Listing 10-39: **Program Source:** Library Segment with Debug Facility

Listing 10-40 shows an application program for a particular intersection where the debug flag is set to TRUE after the macro library is included. As a result, each macro expansion assembles a call to the CP/M operating system to trace the light direction and color change, skipping the machine code which will eventually be assembled to drive the actual *Hornblower* hardware.

```

0100          ORG          100H      ;READY FOR THE DEBUG RUN
          MACLIB INTER      ;BASIC MACRO LIBRARY
FFFF #      DEBUG SET      TRUE    ;READY DEBUG TOGGLE
0100          CYCLE: SETLITE NS,RED
0120          SETLITE EW,GREEN
0142          TIMER      10
0158          SETLITE EW,YELLOW
017B          TIMER      2
0190          SETLITE EW,RED
01B0          SETLITE NS,GREEN
01D2          TIMER      10
01E8          SETLITE NS,YELLOW
020B          TIMER      2
0220          RETRY      CYCLE
023A          END

```

Listing 10-40: **Assembly Listing:** Sample Intersection Program with Debug

The application programmer then uses CP/M to trace the operation of the algorithm, which results in the print-out shown in Listing 10-41. Each trace line corresponds to an invocation of SETLITE with a specific direction and color, with the appropriate wait time between print-outs.

```

NS changing to RED
EW changing to GREEN
timer 10
EW changing to YELLOW
timer 2
EW changing to RED
NS changing to GREEN
timer 10
NS changing to YELLOW
timer 2
retry CYCLE

```

Listing 10-41: **Program Output:** Sample Intersection Program with Debug Trace Output

Upon completion of the initial debugging under CP/M, the SET statement in the application program is removed (the ORG may be removed as well), and the program is re-assembled. This time, the CP/M traces are not included since the debug flag remains FALSE. As a result, the actual *Hornblower* hardware interface is assembled instead. The newly assembled program is then placed into PROM in the controller box for that intersection and tested in its target environment.

This approach to macro based language facilities provides a simple tool for rapid development and debugging of programs where high level languages are not available, but a measure of machine independence is desired. The macros are easy to develop, and the application programs are simple to write and debug.

10.2. Machine Emulation

A second application of macro processing is found in the “emulation” of a machine operation code set which is different from the 8080 microprocessor. In particular, a machine architecture is selected, based upon an existing or fictitious operation code set, and a macro is written for each “opcode,” taking the general form:

```
op      MACRO d1, d2, ..., dN
        opcode emulation
ENDM
```

where “*op*” is a mnemonic instruction in the emulated machine and the dummy parameters *d1* through *dN* represent the optional operands required by “*op*”. The “macro body” includes 8080 instructions which carry-out the operation on the 8080 microprocessor. That is, the instructions within the macro body perform the same function as the “*op*” with its arguments on the emulated machine.

Upon completion of the opcode macro definitions, a program can be written using these opcodes, which expand to the equivalent 8080 instructions, but perform the emulated machine operations.

In order to be specific, consider the situation encountered by *Nachtflieger Maschinenwerke*, an internationally famous manufacturer and distributor of automated machining equipment. Though incorporating microprocessors in controlling their equipment, *Nachtflieger* expects to build a custom LSI processor for their future products. The processor, called the KDF-10 will be used primarily as an analog sensing and control element in a larger electronic environment. As a result, the KDF-10 word size must accommodate digital values corresponding to analog signals of up to twelve bits. In order to allow computations on these twelve bit values, *Nachtflieger* engineers are going to allow a full 16-bit word in the KDF-10, along with a number of primitive operations on these values. Externally, the KDF-10 will provide four analog to digital (A-D) input “Ports” which can be read by KDF-10 programs, along with four digital to analog output ports (D-A) which can be written by the program. The KDF-10 will automatically perform the A-D and D-A conversion at these ports.

Begin forward thinkers, the engineers at *Nachtflieger* have designed the KDF-10 as a “stack machine,” which is similar in concept to the Hewlett-Packard HP-65 hand held programmable calculator, where data can be loaded to the top of a “stack” of data elements, automatically “pushing” existing elements deeper onto the stack. Similar to the Reverse Polish Notation (**RPN**) of an HP-65, arithmetic on the KDF-10 will be performed on the topmost stacked elements, automatically absorbing the stacked operands as the arithmetic is performed. Somewhat simpler than the HP-65, the designers settle upon the following three-character operation codes for the KDF-10:

SIZ n	reserves n 16-bit elements as the maximum size of the KDF-10 operand stack. This operation code must be provided at the beginning of the program.
RDM i	Reads the analog signal from input port i (0, 1, 2, or 3) to the top of the stack, automatically pushing any
WRM o	Writes the digital value from the top of the stack to the D-A output port given by o , (0, 1, 2, or 3). The value at the stack top is removed.
DUP	The top of the KDF-10 stack is duplicated.
SUM	The top two elements of the KDF-10 stack are added, both operands are removed, and the resulting sum is placed on the top of the stack.
LSR n	Performs a logical shift of the topmost stacked element to the right by n bits (1, 2, ..., 15), replacing the original operand by the shifted result. Note that LSR n performs a division of the topmost stacked value by the divisor 2.
JMP a	Branch directly to the program address given by the label a .

Since the KDF-10 does not exist (except in the fertile minds of *Nachtflieger* engineers), the software designers have decided to use the macro facilities of MAC to emulate the KDF-10 using the 8080 microcomputer.

Listing 10-42 shows an example of a program for the KDF-10 which was processed by MAC using the macro library defined by the *Nachtflieger* software group. In this situation, the KDF-10 is connected to four temperature sensors which are attached at strategic places on the machining equipment. The program continuously reads the four input values from the A-D ports and computes their average value by summing and dividing by four. This average value is then sent to D-A output port 0 where it is used to set environmental controls.

```

;      AVERAGE THE VALUES WHICH ARE READ FROM ANALOG
;      INPUT PORTS, WRITE THE RESULTING VALUE TO ALL
;      THE D-A OUTPUT PORTS.
;
MACLIB  STACK  ;READ THE STACK MACHINE OPCODES
SIZ     20      ;CREATE 20 LEVEL WORKING STACK
0000

0156 C32E01    JMP    LOOP ;GO GET ANOTHER SET OF VALUES

```

Listing 10-42: **Assembly Listing:** A-D Averaging Program using “Stack Machine”

Referring to Listing 10-42, the program begins by reserving a stack of 20 elements, which is much larger than required for this application (a maximum of four elements are actually stacked). The program then cycles following “LOOP”, where the values are read and processed. The four operations RDM 0, RDM 1, RDM 2, and RDM 3 read all four temperature sensors, placing their data values in the stack. The three SUM operations which follow the read operations perform pairwise addition of the temperature values, producing a single sum at the top of the stack. Since the average value is desired, the LSR 2 operator is applied to the stack top to perform the division by four. Finally, the resulting average is sent to the D-A port using the WRM 0 operation code. Control then transfers back to LOOP, where the entire operation is performed again.

Since *Nachtflieger* designers are emulating KDF-101s using 8080's, they have created the macro library file, called “STACK.LIB” as shown in Listing 10-43. A macro is shown in this figure for each of the KDF-10 opcodes, starting with the SIZ operator. In this case, the program origin is set (since this must be the first opcode in the program), and the stack area is reserved. Note that double words of storage are reserved since a 16-bit word size is assumed. The DUP, SUM, and LSR operators follow the SIZ macro. In each case, the KDF-10's stack top is assumed to be in the 8080's HL register pair. Further, each operation which pushes the KDF-10 stack causes the element in the 8080 HL pair to be pushed to the 8080 memory area reserved by the SIZ opcode.

```

endm

```

Listing 10-43: **Program Source:** "Stack Machine" Opcode Macros

The DUP opcode simply pushes the HL register pair to memory, since the HL pair is not altered in the 8080 during this operation. In the case of the SUM operator, it is assumed that the KDF-10 programmer has somehow loaded two values to the KDF-10 stack. Thus, it must be the case that the HL registers contain the most recently loaded value, while the 8080 memory stack contains the next-to-most recently stacked value. The POP D operation loads the second operand to the DE pair in the 8080 CPU, then the topmost value and next to top value are added using the DAD D operation. The resulting operand goes into the HL register pair, which is necessary in the KDF-10 emulation, since the top of the KDF-10 stack is located in the 8080's HL register pair.

The LSR opcode is somewhat more complicated. Since the 8080 does not support a double precision (16-bit) right shift of the HL register pair, the values must go through the accumulator. Thus, the LSR macro contains a REPT loop which generates inline machine code for each right shift. The inline machine code performs the right shift by first clearing the carry (XRA A), followed by a high order right shift by one bit (MOV A, H followed by RAR), then by a low order bit shift (MOV A, L followed by RAR). Note that an intermediate bit may move from the high order byte to the low order byte using the carry between high and low order byte shifts.

Referring to Listing 10-43, the RDM and WRM operation codes are defined by "memory-mapped" input/output operations. That is, memory locations 1080H through 1087H are intercepted external to the 8080 microprocessor and treated as external read operations. Thus, a load from location 1080H/1081H to HL is treated as a read from A-D device 0, rather than from random access memory. This operation is simple to perform in the KDF-10 emulation, since all program addresses are assumed to be below 1000H, and thus any 8080 address bus values beyond 1000H must be memory mapped I/O. As a result, ADC0 through ADC3 correspond to the locations where A-D values 0 through 3 are obtained. Similarly, the D-A output values which are written to locations 1090H through 1097H are intercepted as memory mapped output values which are sent to the D-A converters rather than random access memory. The RDM instruction is emulated by simply performing an LHLD from the appropriate memory mapped input address (constructed through concatenation of the dummy parameter). The HL value is first pushed, since the KDF-10 RDM opcode performs this task automatically, then the new value is loaded into the HL register pair. The WRM opcode definition is similar, except the value to write is assumed to reside at the top of the KDF-10 stack (and thus appears in the 8080 HL register pair). The value is written to the memory mapped output location, and the value is removed from the HL pair by restoring HL from the 8080 stack.

In order to see the actual code generated by each of these macros, Listing 10-44 shows the same averaging program as given in Listing 10-42, except that the generated 8080 instructions are interspersed throughout the listing file (Listing 10-44 is the usual output from MAC, while Listing 10-42 was generated using the parameter "-M" which suppresses generated

mnemonics). It is worthwhile cross-referencing Listing 10-42, Listing 10-43, and Listing 10-44 to ensure that the macro expansion processes are clearly understood.

Listing 10-44: **Assembly Listing:** Averaging Program with Expanded Macros

A particular problem arose at *Nachtfliieger MW*, however, which had to be rectified: although programs could be effectively written for the KDF-10 computer using the 8080 emulation, they could not be effectively debugged. The program of Listing 10-44, for example, could be tested under the CP/M debugger (see the *CP/M DDT Users Guide*), but required monitoring and tracing at the 8080 machine code level. It became clear that higher level debugging tools were necessary.

As a result, *Nachtfliieger* designers added several “pseudo opcodes” which allow debugging traces. The opcodes can be interspersed in the program, and selectively enabled and disabled

depending upon the debugging needs. In production, all debugging traces would, of course, be disabled resulting only in absolute port I/O. The additional debugging opcodes are listed below.

PRN <i>msg</i>	Print the message given by “ <i>msg</i> ” at the debugging console whenever the print trace is enabled. The message must be enclosed in broken brackets.
DMP	Print the value of the top element in the KDF-10 stack (in hexadecimal).
TRT <i>t</i>	Set machine code trace option to true. Each time a KDF-10 machine operation is executed, the opcode is printed, followed by the (approximate) KDF-10 machine code address, followed by the top two elements of the KDF-10 stack, in the format: <i>OPC oploc top top'</i> where <i>OPC</i> is the opcode, <i>oploc</i> is the location, <i>top</i> is the top element, and <i>top'</i> is the second to the top element, all in hexadecimal notation.
TRF <i>t</i>	Disable the machine code trace. Only the KDF-10 instructions which physically appear between the TRT and TRF opcodes are shown in the trace.
TRT <i>p</i>	Enable the print/read trace. PRN opcodes which follow produce output at the debugging console, and are otherwise treated as comments. Further, RDM and WRM opcodes prompt and display data at the debugging console.
TRF <i>p</i>	Disable the print/read trace. Only the PRN, RDM, and WRM instructions which physically appear between TRT and TRF interact with the console.

The convention is also taken that the traces are initially disabled at the beginning of the program, and must be explicitly enabled with TRT opcodes.

Listing 10-45 shows the averaging program of Listing 10-42 with interspersed debugging statements. Note that the opcodes TRT *t* and TRT *p* are executed at the beginning of the program, thus enabling all trace options throughout the execution. The PRN statement above the

LOOP label prints the initial sign-on, while the DMP statements after each read operation give the value of the A-D port. Upon completion of the four element read, the PRN opcode is used to indicate this fact. Each SUM operator is followed by a DMP opcode which shows the current sum. Finally, the PRN and DMP opcodes are used to display the final average value which is being sent to D-A port 0. The "XIT" opcode shown at the end of the program will be introduced in the paragraphs which follow.

Listing 10-46 shows the execution of the averaging program under DDT. Note that the program headings appear at the points in the program where PRN opcodes are placed. Further, the console is prompted for input in the case of an RDM opcode (giving the absolute memory mapped input address in decimal), while the WRM instruction produces a "D-A OUTPUT . ." message which shows the absolute memory mapped output address as well as the data which is written. The opcodes are also traced showing the opcode mnemonic, address, and top two stacked elements. The "RDM" trace at the beginning, for example, shows the instruction address HAD, which is in the range of the first RDM of Listing 10-45 (012E and 01EF), and is followed by the two values 0111 (i.e., the value just read) and C21D ("garbage" value, since only one element is stacked). The trace is easily followed at the KDF-10 level, showing each value which is read-in, and the operations performed upon these values. Upon completion of the debugging process under CP/M, the TRT opcodes are removed and the program is reassembled, leaving only the 8080 instructions required in the production machine. *Nachtflieger* systems engineers then take the resulting program and test its operation in a hardware environment.

Forward thinking though they were, *Nachtfliieger* engineers quickly realized that the KDF-10 design had a number of deficiencies due to the paucity of arithmetic operators and the total absence of conditional branching instructions. Further, there was no provision for variable storage other than the stack. Thus, the KDF-11 naturally evolved from the KDF-10, which incorporates these features. In particular, the operation codes of the KDF-11 include:

- | | |
|------------|---|
| DCL v, n | Declare (i.e., reserve) storage for a variable by the name v , with optional size n . If n is omitted, then $n = 1$ is assumed. All DCL opcodes must follow the XIT opcode given below. |
| LIT c | Load the value of the literal constant c to the top of the KDF-11 stack. |

VAL <i>v,i,c</i>	Load the value of the variable <i>v</i> optionally indexed by the variable <i>i</i> with the optional constant offset <i>c</i> . VAL <i>v</i> loads the value of <i>v</i> to the top of the stack, VAL <i>v, I</i> loads the value located at the address of <i>v</i> plus the index value contained in <i>I</i> , while VAL <i>v,I,3</i> loads the value at location <i>v</i> plus the index 1, plus the constant index 3. In all cases, the value is placed at the top of the KDF-11 stack.
STO <i>v,i,c</i>	Similar to the VAL operator, the STO opcode stores the value obtained from the KDF-11 stack to the address given by <i>v</i> , plus the optional index <i>i</i> , plus the optional constant index given by <i>c</i> . The top element of the KDF-11 stack is removed.
DIF	The DIF opcode subtracts the top element of the KDF-11 stack from the next-to-top element of the stack, and replaces both operands by their difference.
GEQ <i>a</i>	The GEQ opcode tests the next to top element (<i>top'</i>) against the top of stack element (<i>top</i>), and branches to the label given by “ <i>a</i> ” if <i>top'</i> is greater than or equal to <i>top</i> . If not, program control continues to the next opcode in sequence.
BRN <i>a</i>	The BRN instruction replaces the JMP instruction in the KDF-10 architecture to allow complete separation of the KDF-11 and 8080 machines.

Listing 10-47, Listing 10-48, and Listing 10-49 give the macro library which was constructed by the *Nachtflieger* software group for KDF-11 machine emulation. Note that over half of the macro library implements trace and debugging functions (Listing 10-47 and Listing 10-48) while the remaining components implement the KDF-11 opcodes themselves. A brief description is given below for each major section of this macro library, called “DSTACK.LIB”, before giving an example of its use.

Listing 10-47: **Library Source:** Stack Machine Macro Library (part A)

Listing 10-47 shows the first portion of the macro library. Since this portion of the library is principally concerned with debugging functions, it begins with CP/M system calls, function numbers, and equates for non-graphic characters, similar to the examples given earlier.

Although these values are not necessary for operation of the KDF-11, they are necessary for the debugging functions which operate when the TRT opcode is in effect. Following the CP/M equates, the “toggles” DEBUGT and DEBUGP are set to false (0 value), which reflect the conditions of the debugging switches given by TRT and TRF. When DEBUGT is true (1 value), machine operation codes are traced. Similarly, when DEBUGP is true, PRN, RDM, and WRM operations interact with the console.

The PRN macro shown in Listing 10-47, for example, produces an inline message with a call to CP/M to write the message whenever the DEBUGP toggle is true; otherwise the PRN produces no generated code.

The UGEN macro which follows PRN in Listing 10-47 is invoked the first time that the debugging subroutines are required by trace or print/read opcodes. When invoked, the UGEN macro produces several inline subroutines which are used throughout the debugging process. If no trace or print/read functions are invoked during the assembly, UGEN is not invoked and thus no inline subroutines are included for debugging. If UGEN is invoked, the subroutines shown below are included inline:

@CH writes a single ASCII character to the console
 @NB writes a single half-byte (nibble) to the console
 @HX writes a full hexadecimal byte value at the console
 @AD writes a full address (double byte) value with preceding blank
 @IN reads a hexadecimal value from the console to HL

Upon including these subroutines, UGEN then redefines itself (see Listing 10-47) to an empty macro body so that the subroutines will not be included upon subsequent invocations of UGEN. This ensures that the inline subroutines will only be included once, and only if they are required by the debugging macros.

Listing 10-48: **Library Source:** Stack Machine Macro Library (part B)

Referring again to Listing 10-49, the `SIZ` macro is similar the opcode defined for the `KDF-10`, except that the `SIZE` of the stack is saved for later declaration in the data area (see the '`XIT`' opcode). The `SAVE` and `REST` macros are used throughout the opcode macros to save and restore the `HL` register pair, based upon the `ACTIVE` flag. The `CLEAR` macro, however, is used to mark the top element of the `KDF-11` stack as deleted.

Continuing with Listing 10-49, the `DCL` macro simply sets up the variable name `VNAME` as a label, and follows the label by a `DS` which reserves the specified number of double words. The `DCL` opcodes must all occur at the end of the `KDF-11` program, following the `XIT` opcode.

Listing 10-49: **Library Source:** Stack Machine Macro Library (part C)

The LIT opcode is emulated with a macro which first SAVES the stack top (possibly generating an HL push). The literal value is then loaded directly into the HL register pair. Note that the ACTIVE flag is set upon completion of this macro, since SAVE always marks HL as active.

The ADR macro in Listing 10-49 is a utility macro which is used in the VAL, STO, and DMP opcodes to build the address of a particular variable (with optional variable and constant offsets) in the HL register pair. Based upon the optional parameters, ADR either loads the base address directly to the HL pair, or constructs the address using HL and DE for indexing. Thus, the invocations of ADR shown to the left below produce the machine code to the right below.

ADR X	LXI	H,X
ADR X,I	LHLD	I
	DAD	H
	LXI	D,X
	DAD	D
ADR X,I,3	LHLD	I
	DAD	H
	LXI	D,6
	DAD	D
	LXI	D,X
	DAD	D
ADR X,,3	LXI	H,6
	LXI	D,X
	DAD	D

thus leaving the final address for the optionally indexed variable in the HL register pair. Note that the code within the ADR macro could be improved slightly in the case that a constant offset is provided. That is, the invocations to the left below could produce the machine code shown to the right below by redefining the ADR macro.

ADR X,I,3	LHLD	I
	LXI	D,X+6
	DAD	D
ADR X,,3	LXI	H,X+6

It is a worthwhile exercise for the reader at this point to redefine ADR to generate this improved machine code sequence.

The VAL and STO macros are shown in Listing 10-49 which load a variable value to the stack, or store the top of stack value to memory, respectively. Note that ADR is used to construct the address of the variable whenever optional indexing is specified. Otherwise, an LHLD or SHLD is used to directly access the variable. Again, slight improvements in generated code could be obtained when only a constant offset is provided with no variable index.

Note that the opcodes `LIT`, `VAL`, and `STO` all end with an invocation of the `?TR` macro which, as discussed above, checks the `DEBUGT` flag. If true, the `?TR` macro invokes `TRACE` with the machine code address and opcode name for display at the debugging console. The `?TR` macro invocation produces no machine code trace when `DEBUGT` is false.

Listing 10-49 contains a listing of the remainder of the “`DSTACK.LIB`” macro library. The `SUM` opcode shown invokes `REST` to ensure that the HL register pair contains the topmost KDF-11 element. The second to top element is then loaded to the DE pair and added to HL, producing an active KDF-11 element in HL. Note that `ACTIVE` is true at this point, since `REST` always leaves the flag set to true.

The `DIF` opcode definition is similar to `SUM`, except the 8080 accumulator is used to compute the 16-bit difference between the top two KDF-11 stacked elements.

Referring to Listing 10-49, the `LSR` macro defines the KDF-11 logical shift right operation. The `REST` macro is first invoked to ensure that HL is active, followed by a repetition of the machine code required to perform a 16-bit right shift of the HL register pair. In the case of a long shift, there will be a considerable amount of inline machine code for the operation. Thus, it is a useful exercise for the reader to redefine `LSR` so that it generates an inline subroutine to perform the shift operation for values of `LEN` which are sufficiently large to warrant the subroutine call.

Although this will require a subroutine set up and call, the amount of generated code could be reduced significantly for programs which make heavy use of the `LSR` operator.

The `GEQ` macro follows the `LSR` definition, and allows conditional branching to the specified label address. `GEQ` begins by computing the difference between the top two elements of the KDF-11 stack which has the side-effect of setting the 8080 carry bit if the next to top element exceeds the top element in the KDF-11 stack. Note that the `?TR` macro eventually leads to the `@TR` subroutine where the status flags (including the carry condition) are saved and restored.

Otherwise, `GEQ` could not generally count on the condition of the carry flag. Further, the 8080 A register contains the least significant difference between DE and HL, hence the `ORA H` produces a zero result if the difference is zero. To be complete, the KDF-11 should have a complete range of conditional tests, allowing tests for equality (`EQL`), inequality (`NEQ`), less-than (`LSS`), greater-than (`GTR`), and less-than-or-equal (`LEQ`). Although *Nachtfliieger* designers intend to include these opcodes in the KDF-12, it may be a worthwhile exercise for the reader to implement these additional macros.

The `DUP` opcode in Listing 10-49 first ensures that the HL register pair is active, then duplicates this value by pushing the HL pair to the 8080 stack, thus emulating a KDF-11 stack push operation. Note that the HL pair is active at the end of the `DUP` macro due to the invocation of `REST`.

The BRN and XIT macros follow GEQ in Listing 10-49. The BRN macro simply translates to a jump instruction in the 8080 while the XIT is slightly more complicated. The XIT macro first invokes the ?TR macro to check for machine code tracing. A “JMP 0” is then emitted corresponding to a system restart in both CP/M and the emulated KDF-11 machine architecture. The XIT macro then produces an “ORG” statement which restarts the assembly process in the data area of the emulated environment (1000H, or 4096 decimal). The area reserved for the stack is then set up (recall that the SIZ macro saves the value of SIZE), followed by the declaration of the label “STACK” at the base of this reserved area. Referring back to Listing 10-49 (middle left), note that the SAVE macro includes the statement sequence

```
IF STACK ;;is it present?
ENDIF
```

which ensures that both the SIZ and XIT macros have been included in the assembly. If the XIT macro had not been included, then the label “STACK” would not appear (unless used in the KDF-11 program), and the “IF STACK” test would produce an undefined operand (U) error. Further, if the XIT operator had been used, but the SIZ had not, then the statement “DS SIZ*2” within XIT would produce an undefined operand message. Although these tests are by no means complete, they will detect the most common errors.

Listing 10-49 also contains the definitions of both the RDM and WRM opcodes, based upon the memory mapped input/output addresses defined by ADC0 through ADC3 for the A-D ports, and DAC0 through DAC3 for the D-A ports. The RWTRACE (Read/Write Trace) macro is included for tracing the RDM and WRM macros when DEBUGP is true. The MSG argument corresponds to either “A-D INPUT” for the RDM opcode, or “D A OUTPUT” for the WRM opcode. The ADR argument corresponds to the absolute decimal address where the memory mapped input/output is taking place. Thus, RWTRACE simply constructs a trace message from its two arguments and passes this message to PRN for display at the debugging console.

The RDM macro reads the port given by the argument “?C” (0,1,2, or 3). The HL register pair is pushed, if necessary, by the SAVE macro (leaving the active flag set for the RDM). RDM then generates an invocation of the RWTRACE macro to produce the trace message. Note that the argument % ADC&?C produces the numeric value of one of ADC0, ADC1, ADC2, or ADC3 which is included in the trace message. If the % were omitted, only the name, not the value, of the input port address would be printed. Following the output message, UGEN is invoked to ensure that the utility subroutines have been included inline. The call to @IN allows the programmer to type a hexadecimal value for the simulated A-D input value, which is subsequently stored to memory and left in the HL register pair (with ACTIVE true). If DEBUGP is not set, then the RDM macro simply loads the HL register pair from the appropriate memory mapped input location. Finally, RDM invokes ?TR to check for possible opcode tracing.

The WRM opcode is similar to the RDM opcode, except that the REST macro is first invoked to ensure that the HL registers contain the top element of the KDF-11 stack. This value is then displayed at the debugging console if DEBUGP is true, and then sent to the appropriate memory mapped output location.

One particular application of the emulated KDF-11 machine shows the power of this particular instruction set. As a small part of a machine control system, a KDF-11 processor monitors the machine tool head motion. *Nachtflieger* engineers connect A-D port 0 to a KDF-11 processor which reads the instantaneous velocity of the tool head at 1 millisecond (ms) intervals. The velocity is provided at the A-D port in micrometer (μm) increments, and the processor is synchronized with the input so that it halts until the 1 ms interval has elapsed. *Nachtflieger* engineers also guarantee that the tool head is in motion for no more than 100 ms before stopping. Thus, with no variations in velocity, if the tool moved at the constant rate of 256 $\mu\text{m}/\text{ms}$ over 50 intervals of 1 ms each, the total distance travelled by the tool is

$$256 \mu\text{m}/\text{ms} * 50 \text{ ms} = 1280 \mu\text{m} = 1.280 \text{ mm}$$

During its travel, however, the instantaneous velocity of the tool head varies according to the roughness of the cut, wear on the parts, and start/stop intervals. *Nachtflieger* uses the data collected during a particular cut to monitor these factors, and displays machine operator information in both digital and analog forms. A primary function of the KDF-11 processor in this particular case is to collect the instantaneous velocities during a single cut, and hold these values for analysis as the tool returns to its starting position. Listing 10-50 shows a KDF-11 program which includes the data collection phase, as well as an analysis phase described below.

The data collection phase of Listing 10-50 occurs between the labels MOVE? and COMP, while the analysis phase is found between labels COMP and ENDF. Note that the program is bounded by the SIZ operator at the beginning, along with the XIT operator at the end, followed by DCL opcodes which reserve data areas. This particular program also includes debugging PRN, DMP, TRT, and TRF opcodes for checking out the program.

Listing 10-50: **Assembly Listing:** Program for Tool Travel Computation

Referring to the DCL statements at the end of Listing 10-50, the “vector” v is declared with length 100 (double bytes), which will hold the collected velocities, while I and x are temporary

values used during the collection and analysis phase. The variable TOTAL is a result produced by the analysis as discussed below.

The program collects data by performing the following steps. The variable I is first initialized to 0, corresponding to the first velocity $v(0)$. The program then examines the A-D input port for the first non-zero velocity, waiting for the tool head to begin its travel. When the first non-zero velocity is read, the collection process proceeds by storing the first value at $v(0)$. The index value I is then moved along as data items are read, with values placed into $v(1)$, $v(2)$, and so-forth, until a zero value is read, indicating the tool has ended its travel.

Referring to Listing 10-50, note that the KDF-11 opcodes listed before the label MOVE? initialize the index I by loading a literal 0 value to the KDF-11 stack, followed by a store into the variable I. In order to follow these operations, the TRT P and TRT T traces are enabled. Note, however, that the TRF T opcode stops the machine code trace immediately before the MOVE? label.

Following the MOVE? label, A-D port 0 is read and examined for the first non-zero value. Each time the port is read it is stored into the temporary variable X, then reloaded and examined for a zero value. Since GEQ is the only comparison operator in the KDF-11 machine, the test is “I greater than or equal to X”. Thus, the branch is taken to READ whenever X is 1 or larger.

Upon encountering the READ label, the value X (just read from port 0) is stored into VW, where I is zero. The value of I is then incremented by loading I to the top of the KDF-11 stack, adding 1 (LIT 1, SUM), and then storing the sum back into I. After incrementing I, the program proceeds to check the end of the tool travel. X is loaded to the top of the stack, and the test “0 greater than or equal to X” is performed. If the condition is true, control transfers to the label COMP, where the analysis phase begins. Otherwise, port 0 is read again and the value is stored into the temporary X. Control then proceeds back to the READ label to store the next velocity, and test for zero.

Before 100 intervals have elapsed, the RDM 0 produces a zero value which is stored into X and subsequently stored into $v(I)$, for the current value of I. Thus, when control arrives at the label COMP, the instantaneous velocities are stored in v , terminated by a zero. At this point, the analysis of these collected velocities can take place.

The single function which takes place in the analysis section of Listing 10-50 is the computation of the distance travelled by the tool through this interval. In particular, *Nachtflieger* engineers have determined that it is sufficient to compute the distance travelled by the tool using the “trapezoidal rule” which approximates the actual distance by summing the average of each adjacent pair of velocities. The sums are formed as shown below:

$$\frac{V_0+V_1}{2} + \frac{V_1+V_2}{2} + \dots + \frac{V_{n-1}+V_n}{2}$$

where n is the last interval to sum. Thus, for example, if the velocity is constant at 256 $\mu\text{m/ms}$ (which wouldn't occur in practice), then

$$V_1 = V_2 = \dots = V_n = 256$$

and the summing formula given above reduces to $256 * n$. Given the example above where $n = 50$ ms, the above formula produces the value 1.280 mm, as given earlier. In general, the velocity values will not be constant, hence the numerical integration given by the trapezoidal rule is used to obtain an approximation.

The KDF-11 instructions shown in Listing 10-50 between the COMP and ENDF labels perform the numeric integration given by the trapezoidal rule. In general, the temporary I is used to index through the velocity vector V until the final zero value is encountered. For each interval, the values of two adjacent velocities are summed and divided by two. Each result is then summed into TOTAL, where the values are accumulated until the final zero velocity is discovered.

The opcode sequence immediately following COMP places a zero value at the top of the KDF-11 stack, then stores this value into both the index I and the accumulating sum given by TOTAL. Ignoring the trace opcodes, the operations following GETNXT read the starting point of the next interval to process into the stack, using VAL V, I (value of V, indexed by I). If 0 is greater than or equal to this value then the computation is complete and control goes to the label ENDF. Otherwise, the value of V(I) is loaded to the KDF-11 stack, followed by the value of V(I+1). The loaded values are then summed (SUM) and divided by two (LSR 1), producing a value which remains in the KDF-11 stack. TOTAL is then loaded and added to this partial sum and the result is stored back to TOTAL. The index value I is then incremented to the next interval and processing continues back at the loop header GETNXT.

Upon processing the final zero velocity, control reaches the ENDF label where the distance travelled is written to D-A output port zero. The output value is sent to external instrumentation which processes the result and displays the distance travelled in a form which is readable by the tool operator.

Note that debugging statements have been placed throughout the program which can be used to trace the program execution. Listing 10-50 also contains TRT operators which have enabled trace code generation, and thus this particular program, although longer than the final production version, can be used to follow execution under CP/M.

Listing 10-51 shows the execution of the program of Listing 10-50 under DDT. The messages printed at the debugging console are a result of the PRN opcodes distributed throughout the original program which were enabled through the TRT P opcode. Further, the machine code trace was only enabled for the interval of two operation codes (LIT and STO) at the beginning. In order to test this program, simple A-D values were supplied at the console for the velocities:

$$V_0 = 100_{16}, V_1 = 120_{16}, V_2 = 100_{16}, V_3 = 80_{16}, V_4 = 0_{16}$$

Upon detecting the final 0 value, the trace of Listing 10-51 shows the first 10 values of v (the last 5 elements are “garbage” values), followed by a trace of the sum operations for each interval. In each case, the pairs of values which are being added are displayed (using the DMP opcode), followed by their summed value, along with the running total. Upon completion of the distance computation, the value 320H is sent to the D-A output port and displayed at the console.

Listing 10-51: **Debug Session:** Sample Execution of "Distance" using DDT

Upon completion of initial checks under CP/M, *Nachtfliieger* programmers remove the TRT and TRF statements from the KDF-11 program and reassemble producing only the absolute input/

output instructions required for machine tool control. The resulting program, which produces much less code than the debugging version, is placed into the equipment for further testing and evaluation.

Listing 10-52 is also provided as an example of the listing which is produced when all machine code operators are traced. Although the source program listing is not shown, it is identical to Listing 10-50 except that the TRF T opcode is removed. Since the complete trace is quite extensive, only a partial execution is shown in Listing 10-52.

In summary, *Nachtflieger MW* has derived several benefits from their emulation of the KDF series stack machines. First, there is very little cost involved in designing and altering their machine architecture. In fact, current prices for 8080 microcomputers may preclude the custom LSI version of the KDF-? machine. A second advantage of the KDF emulation is that the KDF programs are highly independent from the host processor. That is, given that a higher performance or less expensive processor becomes available to *Nachtflieger*, the existing programs can be used intact by only changing the macro definitions for each of the KDF opcodes and reassembling using MAC or an equivalent macro processor. Lastly, machine emulation through macro defined operation codes offers a distinct advantage over interpretive approaches since each opcode translates to only a few host machine operations. Interpretive execution often involves ratios of 1000 to 20,000 emulated instructions per host instruction, while macro based opcodes are often in a ratio of less than 10 to 1. Further, interpretive processors usually require run-time support consisting of a predefined general-purpose subroutine package which is included for each and every program. Thus, for a wide variety of microcomputer applications, machine emulation through macro defined op codes offers distinct advantages over alternative approaches.

10.3. Program Control Structures

Macro facilities can be used to provide program control statements which resemble those found in many high-level languages. In general, program control statements allow boolean tests and conditional branching based upon the outcome of the boolean test. Further, label names which would normally be provided by the programmer as the destination of a branch are automatically generated for the particular statement.

In the paragraphs which follow, three typical control statements are presented which allow simple conditional grouping (`WHEN-ENDW`), controlled iteration (`DO ENDDO`), and case selection (`SELECT-ENDSEL`). In all three cases, the intention is to define program control facilities which allow well-structured programming, resulting in programs which are easier to write, debug, and maintain.

Two libraries are first introduced in order to provide a foundation for further discussion. The I/O library shown in Listing 10-53 allows simple character input operations along with full message output. The `READ` macro accepts a single character from the console keyboard and stores this character into the variable given by the parameter `"VAR"`. The `WRITE` macro shown in Listing 10-53 takes an ASCII message as a parameter and sends this message to the console output device preceded by a carriage-return line-feed sequence. These simple I/O macros are stored on the diskette in the file `"SIMPIO.LIB"` and are used in the examples which illustrate the control structures.

```

Listing 10-53: **Library Sources:** Simple I/O Macro Library

The second library used in the control structure examples is given in Listing 10-54. Collectively, these macros define a number of boolean operations which are performed upon 8-bit operands, providing the basic relational operations on unsigned integer values, including:

- LSS** Less Than
- LEQ** Less Than or Equal To
- EQL** Equal To
- NEQ** Not Equal To
- GEQ** Greater or Equal
- GTR** Greater Than

In all cases, the macros accept three actual parameters, consisting of two data values involved in the test (x and y), along with a program label which receives control if the boolean test produces a true value (TL). The first operand x can be a labelled memory location containing an 8-bit value, and y can be either a labelled 8-bit location or a literal numeric value. If the first operand x is not supplied, then the value to be tested is assumed to exist in the 8080 accumulator when the macro is entered.

```

test? macro x,y
;; utility macro to generate condition codes
if not nul x ;;then load x
lda x ;;x assumed to be in memory
endif
tdig? irpc ?y,y ;;y may be constant operand
set '&?Y'-'0' ;;first char digit?
exitm ;;stop irpc after first char
endm
if tdig? <= 9 ;;y numeric?
sui y ;;yes, so sub immediate
else
lxi h,y ;;y not numeric
sub m ;;so sub from memory
endm

;
lss macro x,y,t1
;; x lss than y test,
;; transfer to t1 (true label) if true,
;; continue if test is false
test? x,y ;;set condition codes
jc t1
endm

;
leq macro x,y,t1
;; x less than or equal to y test
lss x,y,t1
jz t1
endm

;
eq macro x,y,t1
;; x equal to y test
test? x,y
jz t1
endm

;
neq macro x,y,t1
;; x not equal to y test
test? x,y
jnz t1
endm

```

```

;
geq      macro    x,y,t1
;;      x greater than or equal to v test
        test?    x,y
        jnc      t1
        endm

;
gtr      macro    x,y,t1
;;      x greater than y test
        local    fl          ;;false label
        test?    x,y
        jc       fl
        dcr      a
        jnc      t1
fl:      endm

```

Listing 10-54: **Library Sources:** Macro Library for Simple Comparison Operations

Thus, for example, the macro invocation

```
LSS ALPHA,BETA,TRUECASE
```

compares the values stored at the labelled memory locations ALPHA and BETA (defined by a DS or DB statement), and transfers to the program step labelled by TRUECASE if ALPHA contains a value less than the value stored at BETA. The invocation

```
LSS ,BETA,TRUECASE
```

is similar, but compares the contents of the 8080 accumulator with the value stored at BETA.

Finally, the invocation

```
LSS ALPHA,34,TRUECASE
```

compares ALPHA with the literal value 34 in the relational test.

Note that the macro TEST? is used throughout the macro library to construct the relational test by first loading the initial operand x, if necessary. The second operand type is then examined by executing an “IRPC” within the TEST? macro of Listing 10-54 which extracts the first character of the Y operand. This first character must be either numeric or alphabetic. If numeric, then the literal value is subtracted from the accumulator, setting the 8080 condition codes. If the first character of Y is non-numeric then the value is assumed to reside in memory. In this case, the HL registers are set to the Y operand and the value at Y is subtracted from the accumulator value. In any case, the 8080 condition codes are set as a result of the subtraction operation. These condition codes are then used in the individual macros to produce conditional jumps to the destination labels. These macros are collectively stored on the diskette in a file named “COMPARE.LIB” for use in examples which follow.

Listing 10-55 shows an example of a program which uses both the SIMPIO and COMPARE libraries. The purpose of this program is to successively read console characters and print messages

```

0100          ORG      100H
              MACLIB   SIMPIO          ;SIMPLE 10 LIBRARY
              MACLIB   COMPARE         ;COMPARISON OPERATORS
              ;
0100          CYCLE:   WRITE    <TYPE A CHARACTER FROM A TO D >
0112          READ     X
              ;
011A          TEST    FOR LOWER CASE ALPHABETIC
              LSS      X,61H,NOTRAN
              ;
              ARRIVE HERE IF X IS GREATER OR EQUAL TO
              ;
              A LOWER CASE A (=61H), TRANSLATE
0124 3ACD01     LDA     X
0127 E65F       ANI     5FH             ;CLEAR LOWER CASE BIT
0129 32CD01     STA     X             ;STORE BACK TO X
              NOTRAN:
              ;
              ;
              ;
012C          NEQ      X,%'A',NOTA
0136          WRITE    <YOU TYPED AN A>
0148 C30001     JMP     CYCLE
014B          NOTA:   NEQ      X,%'B',NOTB
0155          WRITE    <YOU TYPED A B>
0167 C30001     JMP     CYCLE
016A          NOTB:   NEQ      X,%'C',NOTC
0174          WRITE    <YOU TYPED A C>
0186 C30001     JMP     CYCLE
0189          NOTC:   NEQ      X,%'D',ERROR
0193          WRITE    <YOU TYPED A D>
01A5          WRITE    <BYE^!>
01B7 C9        RET
01B8          ERROR:  WRITE    <NOT AN A, B, C, OR D>
01CA C30001     JMP     CYCLE
01CD          X:      DS       1          ;TEMP FOR CHARACTER
01CE          END

```

In comparing each letter, the macro `NEQ` is invoked with the first argument corresponding to the character typed at the console (`x`), while the second argument corresponds to the letter to match. Note that the `"%"` operator is used in each case to produce the numeric value of the character. This is necessary since the `TEST?` macro expects either a number or a label value in the second argument position. The program processes characters until a `"D"` is typed at which time it returns to the console command processor. The intention here is to show the use of boolean tests used by the control structure macros which follow.

119

abstracted, however, and does not show the macro library statements or the remainder of the program following the NOTA label.

Listing 10-56: **Assembly Listing:** COMPARE with Macro Expansion

The macro library shown in Listing 10-57, called NCOMPARE, expands upon the basic relational macros by allowing a “false branch” option. That is, each macro accepts four arguments: the X and Y operands, as before, as well as a “true label” (TL) and “false label” (FL). It is assumed that either the TL or FL will be supplied in any particular invocation of a relational operator, but not both. If the TL is supplied, then the branch is taken if the relational operator produces a true result. Conversely, if the TL label is absent but the FL label is supplied, then the branch to FL is taken if the relational operation produces a false result. Thus, NCOMPARE expands upon the COMPARE library by allowing all of -the relational operation as well as their negations. Using the NCOMPARE library, for example, the macro invocation

```
LSS X,20,,FALSELAB
```

branches to the label FALSELAB if X is not less than the value 20. One should note that the negation operations are accomplished within the NCOMPARE library by first testing for a null TL

operand and, if empty, the relational operation is reversed by invoking the appropriate negated macro. For example, the LSS macro in Listing 10-57 invokes the GEQ macro, which is equivalent to “not LSS” when the TL argument is empty and supplies the FL argument to LSS as the TL label to GEQ. These negated relational forms will be used within the control structures which are described below.

```

;      macro library for 8-bit comparison operation
;
test?  macro  x,y
;;      utility macro to generate condition codes
      if      not nul x          ;;then load x
      lda     x                  ;;x assumed to be in memory
      endif
      irpc    ?Y,y              ;;y may be constant operand
tdig?  set     '&?Y'-'0'        ;;first char digit?
      exitm   ;;stop irpc after first char
      endm
      if      tdig? <= 9        ;;y numeric.
      sui     y                  ;;yes, so sub immediate

        jnc     t1
gfl:     endm

```

Listing 10-57: **Library Source:** Expanded NCOMPARE Comparison Operators

Listing 10-58 gives an example of the use of the NCOMPARE library within a particular program. This program is similar to the previous example, but instead checks to insure that alphabetic translation only occurs within the proper range of lower case letters. Following the label CYCLE, the character read from the console is compared with a lower case “a” (using the % operation to produce the equivalent decimal value 97). Since the negated form of GEQ is used here, the label NOTRAN receives control if x is not greater than or equal to %Y. If x is greater than or equal to “a”, program flow continues to the next test in sequence where x is compared with a lower case “z” (%‘z’ = decimal 122). In this case, the normal form of GTR is used and thus control transfers to NOTRAN if x is greater than %‘z’ which is above the range of lower case alphabetic characters. If x is between %‘a’ and %‘z’, the character is changed to upper case, as before, by removing the lower case bit and replacing x in memory. Note that the indentation levels between the GEQ and GTR operations are included for readability of the program.

```

Listing 10-59: **Assembly Listing:** NCOMPARE Sample with “+M” Option

Given the SIMPIO and NCOMPARE libraries, it is now possible to define the first complete control structure, called the WHEN-ENDW group. The form of the group is:

```

WHEN condition
  statement-1
  statement-2
  ...
  statement-n
ENDW

```

where “*condition*” is a relational expression taking one of the forms

id,rel,id *id,rel,number* *,rel,id* *,rel,number*

and “*id*” is an identifier, “*rel*” is a relational operator (LSS, LEQ, EQL, NEQ, GEQ, GTR), and “*number*” is a literal numeric value. Similar in form to the arguments of the individual relational operators of the COMPARE library, the last two forms shown above assume the first argument is present in the 8080 accumulator. The meaning of the WHEN-ENDW group is as follows: the condition following the WHEN is evaluated as a relational expression, according to the rules stated with the COMPARE library. If the condition produces a true result, then *statement-1* through *statement-n* are executed. Otherwise, control transfers to the statement following the ENDW. Nested WHEN-ENDW groups are allowed when they take the form:

WHEN . . .

WHEN . . .

WHEN . . .

ENDW

ENDW

ENDW

to arbitrary levels, where the represent interspersed statements. Because of the simplified implementation, nested parallel WHEN-ENDW groups are disallowed when they take the form:

WHEN . . .

WHEN . . .

ENDW

WHEN . . .

ENDW

ENDW

The implementation of the WHEN-ENDW group is based upon macros which “count” WHEN-ENDW groups and generate branches and labels at the proper levels in the structure.

```

;      macro library for "when" construct
;
;      label generators
genwtst macro   tst,x,y,num
;;      generate a "when" test (negated form),
;;      invoke macro "tst" with parameters
;;      x,y with jump to endw & num
      tst      x,y,,endw&num
      endm

;
genlab  macro lab,num
;;      produce the label "lab" & lnum"
lab&num:
      endm

;
;      "when" macros for start and end
;
when    macro xv,rel,yv
;;      initialize counters first time
wcnt    set     0          ;;number of whens
when    macro   x,r,y
      genwtst r,x,y,%wcnt
wlev    set     wcnt      ;;next endw to generate
wcnt    set     wcnt+1    ;;number of "when"s
      endm
      when     xv,rel,yv
      endm

;
endw    macro
;;      generate the ending code for a "when"
      genlab endw,%wlev
wlev    set     wlev-1    ;;count current level down
;;      wlev must not go below 0 (not checked)
      endm

```

Listing 10-60: **Library Source:** Macro Library for the WHEN Statement

Listing 10-60 shows the WHEN macro library, consisting of four macros GENWTST (generate WHEN test), GENLAB (generate label), WHEN (beginning of WHEN group), and ENDW (end of WHEN group). These macros, in turn, use the macros in the NCOMPARE library shown previously and thus are assumed to exist in the user's program as a result of a MACLIB NCOMPARE statement. Label generation is based upon the WCNT (WHEN count) and WLEV (WHEN level) counters. WCNT is incremented each time a WHEN is encountered, and WLEV keeps track of the number of WHEN's which have occurred without corresponding ENDW's.

Upon encountering the first WHEN, the WCNT and WLEV counters are set to zero, and the WHEN macro is redefined to generate the first WHEN test by invoking GENWTST, using the relation R, operands X and Y, and WHEN counter WCNT. Note that the value of WCNT is passed to GENWTST rather than the characters "WCNT" themselves. Thus, at the first invocation of GENWTST, the dummy argument NUM has the value 0. The first argument to GENWTST, called TST, corresponds to

a relational operation MSS through GTR) and thus is invoked automatically within the body of GENWTST, using the negated form of the relational since the TL argument is empty. Again referring to the body of the GENWTST macro in Listing 10-60, note that the last argument, corresponding to the false label of the relational operation, is the constructed label ENDW&num, where *num* has the value 0 initially, and successively larger values on later invocations. Each time GENWTST is invoked, it generates a relational test and a branch on false to a generated label. It is the responsibility of the ENDW macro to produce the appropriate balanced label when encountered in the program.

Referring back to the body of the WHEN macro in Listing 10-60, the WLEV level counter is set to the current WCNT, and the WCNT is incremented in preparation for the next WHEN statement. Similar to nearly all macros which redefine themselves, the outer macro definition of WHEN invokes the newly created WHEN macro before exit.

Upon encountering the an ENDW statement in the source program, the ENDW macro first invokes GENLAB to generate the appropriate ENDW label. The first argument to GENLAB is the label prefix ENDW, while the second argument is the evaluated parameter %WLEV corresponding to the current ENDW label. If only one WHEN statement had been encountered, for example, the value of WLEV would be zero, and thus GENLAB would produce the label ENDW0 which is the destination of the earlier branch. generated by an invocation of GENWTST. Following the invocation of GENLAB, WLEV is decremented to account for the fact that one more destination label has been resolved.

As an example of the use of WHEN-ENDW, Listing 10-61 shows a sample program which resembles the previous character scanning function, but uses the WHEN group in the place of simple tests and branches. As before, a single character is read from the console and first tested for possible case conversion. The statement “WHEN

X,GEQ,61H” causes the three statements which follow to be executed when x is greater than or equal to 61H (lower case “a”) and skipped otherwise. Further, the four WHEN groups which follow each test for the specific characters A, B, C, or D. If an “A” is typed, the corresponding WHEN group is executed, and control transfers back to the CYCLE label where another character is read from the console. If the letter “D” is typed, the program responds with two messages and returns to the console command processor.

Listing 10-61: **Assembly Listing:** Sample WHEN Program with “-M” in Effect

Listing 10-62 shows the same program with full macro trace enabled. This particular portion of the program shows macro processing for the first WHEN-ENDW group only, although the remaining groups are processed in a similar fashion. It is a worthwhile exercise for the reader to determine that the nesting rules for WHEN groups are properly stated, and that the restriction on nested parallel groups is, in fact, necessary.

Listing 10-62: **Assembly Listing:** Sample WHEN Program with “+M” (Part)

A second control structure, called the DOWHILE-ENDDO group takes the general form

```

DOWHILE condition
    statement-1
    statement-2

    statement-n
ENDDO

```

where the “condition” and nesting rules are identical to the WHEN-ENDW group. The DOWHILE group is similar in concept to the WHEN group, except that statements 1 through n are executed repetitively as long as the condition remains true. That is, the condition is evaluated when the DOWHILE is encountered in normal program flow. If the condition produces a false value, then control transfers to the statement following the ENDDO. Otherwise, the statements within the

group are executed until the ENDDO is reached. Upon encountering the ENDDO, control transfers back to the DOWHILE and the condition is evaluated again. Iteration continues through the group until the condition produces a false value.

The macro library for the DOWHILE group is shown in Listing 10-63. In general, the DOWHILE statement invokes the relational operator macros to produce the proper sequence of tests and branches. Upon encountering the ENDDO, the proper label and jump sequence is again generated. Note that the only essential difference in the DOWHILE and WHEN groups is that the location of the DOWHILE test must be labelled and a JMP instruction must be generated to this label at the end of each group.

Referring to Listing 10-63, GENDTST (generate DOWHILE test), GENDLAB (generate DOWHILE label), and GENDJMP (generate DOWHILE jump) are all “label generators” used in the macros which follow. Similar to the WHEN macro, DOWHILE uses the counters DOCNT and DOLEV to keep track of the number of DOWHILE groups which have been encountered along with the current DOWHILE level, corresponding to the number of unmatched DOWHILE’s. The DOWHILE macro first generates the entry label DTEST n , where n is the DOWHILE count. The conditional test is then generated, similar to the WHEN macro, with a branch on false condition to the ENDD n label which will eventually be generated by the ENDDO macro. Finally, the DOWHILE macro increments the DOCNT counter in preparation for the next group.

```

;      macro library for "dowhile" construct
;
gendtst macro    tst,x,y,num
;;      generate a "dowhile" test
;      tst      x,y,,endd&num
;      endm

;
gendlab macro lab,num
;;      produce the label lab & num
;;      for dowhile entry or exit
lab&num:
;      endm

;
gendjmp macro    num
;;      generate jump to dowhile test
;      jmp      dtest&num
;      endm

;
;      dowhile macro xv,rel,yv
;;      initialize counter
docnt set      0          ;number of dowhiles
;;
dowhile macro x,r,y
;;      generate the dowhile entry
;      gendlab dtest,%docnt
;;      generate the conditional test
;      gendtst r,x,y,%docnt
dolev set      docnt      ;;next endd to generate
docnt set      docnt+1
;      endm
;      dowhile xv,rel,yv
;      endm

;
enddo macro
;;      generate the jump to the test
;      gendjmp %dolev
;;      generate the end of a dowhile
;      gendlab endd,%dolev
dolev set      dolev-1
;      endm

```

Listing 10-63: **Library Source:** Macro Library for the DOWHILE Statement

The ENDDO macro in Listing 10-63 first generates the JMP instruction back to the DOWHILE test, using the GENDLAB utility macro, and then produces the ENDDn label which becomes the target of the jump on false condition. The form of the expanded macros for one nested level thus becomes:

```

DTESTO:
;conditional jump to ENDDO
DTESTL:
;conditional jump to ENDD1

```

```
JMP DTEST1
```

```
ENDD1
```

```
JMP DTEST0
```

Listing 10-64 shows an example of a program which uses the DOWHILE group. Although this program differs slightly from the previous examples, the principal function is the same: a STOP character is first read from the console, followed by a group of statements which repetitively execute in search for the STOP character. Two DOWHILE groups occur within the program. The first group checks each character typed M to see if it matches the STOP character. If not (“DOWHILE X,NEQ,STOP”) the statements up through the matching ENDDO are processed. If the value of X is the character A, then the message “YOU TYPED AN A” is sent to the console. Otherwise, the message “NOT AN A” is typed, followed by a check to see if the STOP character was typed. If so, the messages “STOP CHARACTER” and “BYE!” appear at the console. In this case, control continues through the ENDW’s to the ENDDO and back to the DOWHILE header. In this case, the “DOWHILE X,NEQ,STOP” produces a false condition, and control transfers to the “XRA A” instruction following the ENDDO.

Listing 10-64: **Assembly Listing:** An Example using the DOWHILE Statement

Referring again to Listing 10-64, a second DOWHILE-ENDDO group is executed which clears the normal CRT screen size of 23 lines. This is accomplished by first setting X to the value zero,

Listing 10-65 shows a portion of the program of Listing 10-64, with partial macro trace enabled. Note in particular that this trace does not show the generated labels ENDD1 and DTEST1 since no machine code was generated on those lines (the “+M” assembly parameter would show the labels, however). The locations of these labels can be derived from the “hex” listing to the left by noting that the “JNC ENDD1” produces the destination address “01FF” corresponding to the “RET” statement, while the “JMP DTEST1” produces the address “01E2” corresponding to the “LDAX” instruction at the beginning of the DOWHILE group.

```

The last control structure presented in this section is the SELECT-ENDSEL group, which corresponds to the Fortran “computed GO-TO,” the ALGOL “switch” statement, and the PL/M “case” statement. The general form of the SELECT group is

```

SELECT  id
      statement-set-0
SELNEXT
      statement-set-1
SELNEXT
      ...
SELNEXT
      statement-set-n
ENDSEL

```

where “*id*” is a data label corresponding to an 8-bit value in memory, and statement set 0 through *n* denote groups of statement separated by SELNEXT delimiters.

The action of the SELECT-ENDSEL group is as follows: the variable given in the SELECT statement is taken as a “case” number assumed to be in the range 0 through *n*. If the value is 0, *statement-set-0* is executed and, upon completion of the group, control transfers to the statement following the ENDSEL. If the variable has the value 1, then *statement-set-1* is executed. Similarly, if the variable produces a value *i* between 0 and *n*, then *statement-set-i* receives control. There can be up to 255 groups of statements within each SELECT-ENDSEL group, and any number of distinct SELECT-ENDSEL groups. Nested SELECT-ENDSEL groups are not allowed, however. That is, a SELECT-ENDSEL group cannot occur within a statement-set enclosed within an encompassing SELECT-ENDSEL group. As a convenience, the variable following the SELECT can be omitted in which case the current 8080 accumulator content is used to select the proper case.

Listing 10-66 and Listing 10-67 show the SELECT macro library which implements the SELECT-ENDSEL group. The general strategy is to count the cases as they occur, starting with the SELECT, delimited by NEXTSEL, and terminated by ENDSEL. As the cases occur, a case label is generated which takes the form CASE $n@m$ where *n* counts the SELECT-ENDSEL groups, and *m* is the case number within group *n*. A jump instruction is generated at the end of each case to the label ENDS n which marks the end of the SELECT group number *n*. Upon encountering the end of the group, a “select-vector” is generated which contains the address of each case within the group, headed by the label SELV n , where *n* is again the group number. Machine code is thus generated at the SELECT entry which indexes into the select vector, based upon the SELECT variable, to obtain the proper case address. The first statement within the case receives control based upon the value obtained from this vector.

```

;      macro library for "select" construct
;
;      label generators
genslxi macro    num
;;      load hlwith address of case list
        lxi      h,selv&num
        endm

;

        endm

```

Listing 10-66: **Library Source:** Macro Library for SELECT Statement

The general form of the machine code generated for the first SELECT group within a particular program (group $n = 0$) is:

```
LDA id
LXI SELV0
    (index HL by id, and
    load the address to HL)
PCHL
CASE0@0:
    statement-set-0
JMP ENDS0
CASE0@1:
    statement-set-1
JMP ENDS0
CASE0@n:
    statement-set-n
JMP ENDS0
SELV0:
    DW CASE0@0
    DW CASE0@1
...
    DW CASE0@n
ENDS0:
```

Listing 10-66 contains the label generators GENSLXI (generate SELECT LXI), GENCASE (generate case labels), GENELT (generate select vector element), and GENSLAB (generate SELECT label). Listing 10-67 contains the macro definitions for SELNEXT (select next case), SELECT, and ENDSEL. Referring to Listing 10-67, the SELECT macro begins by zeroing CCNT which counts SELECT-ENDSEL groups and then redefines itself, similar to the WHEN and DOWHILE macros. The redefined SELECT macro then generates the select vector indexing operation by loading the indexing variable, if necessary, and then fetches the specific case address. Note that no machine code is generated to check that the indexing variable is within the proper range. The PCHL at the end of this code sequence performs the branch to the selected case. At the end of the redefined select macro, SELNEXT is invoked automatically to delimit the first case in the SELECT group (otherwise SELECT would have to be followed immediately by SELNEXT in the user program to generate the proper labels. SELECT also zeroes the ECNT variable which counts the cases until ENDSEL is encountered.

```

selnext macro
;;      generate the next case
      gencase %ccnt,%ecnt
;;      increment the case element count
ecnt    set      ecnt+l
      endm

;
select macro  var
;;      generate case selection code

      genslab %ccnt,%ecnt          ;;case list
;;      increment "select" count
ccnt     set      ccnt+l
      endm

```

Listing 10-67: **Library Source:** Library for SELECT Statement (continued)

SELNEXT, shown at the top of Listing 10-67, is invoked by the programmer to delimit cases. The GENCASE utility macro is invoked which, in turn, generates a JMP instruction for the previous group, if this is not group zero, and then produces the appropriate case entry label. SELNEXT also increments the select element counter ECNT to account for yet another case.

Upon encountering the ENDSSEL, the last macro in Listing 10-67, GENCASE is again invoked to generate the JMP instruction for the last case. GENSLAB then produces the select vector by first generating the SELVn label, followed by a list of ECNT DW statements which have the case label addresses as operands. Listing 10-68 gives an example of a simple program which uses two SELECT groups. The first SELECT group executes one of five different MVI instructions based upon

the value of X. The second SELECT group assumes that the 8080 accumulator contains the selector index, and executes one of three different MVI instructions. The program of Listing 10-68 is used only to illustrate the generated control structures, and does not itself produce any useful values as output. The sorted symbol table shown at the end of the listing gives the generated label addresses for the individual cases.

```

Listing 10-69: **Assembly Listing:** SELECT Example with Mnemonics “+L”

Listing 10-70 gives a more complete trace of the SELECT-ENDSEL group, showing the actions of the macros as they expand for the second SELECT-ENDSEL group of Listing 10-68. The listing has been edited to remove the case selection code, which is listed in Listing 10-69, as well as the code generated for case number 2. Listing 10-70 should be cross-referenced with the SELECT macro library given in Listing 10-66 and Listing 10-67 if confusion remains as to the actions of these macros.

Listing 10-70: **Assembly Listing:** SELECT Example with “+M” Option

It is now possible to show a complete program which uses the WHEN, DOWHILE, and SELECT groups. Listing 10-71 shows a program which is similar in function to a more complicated program which interacts with the console in executing single character input commands. In fact, the two CP/M programs ED and DDT both take this general form (see the ED and DDT *Users Guides* for details). That is, a single letter is used to select a single action which may correspond to an edit request in the ED program, or a debug request in DDT. Upon completion of each command, control returns back to the main loop to accept another single letter command.

The program given in Listing 10-71 begins by loading the macro definitions for the SIMPIO, NCOMPARE, WHEN, DOWHILE, and SELECT operations. Several messages are then sent to the console device, followed by a single DOWHILE - ENDDO group which encompasses nearly the entire program. The DOWHILE group is controlled by the X,NEQ,%'D' test and thus continues to loop while the x character is not the letter “D”. On each iteration of the DOWHILE group, a single letter is read from the console and converted to upper case, if necessary. In order to ensure that the

letter is in the proper range of values, two WHEN groups follow which convert illegal values to the letter "E" which will subsequently produce an error response.

```

```

Listing 10-71: **Assembly Listing:** Program using WHEN, DOWHILE and SELECT

Following the WHEN tests in Listing 10-71, the character must be in the range 'A' through 'E'. Before indexing into the SELECT group, this value is "normalized" to the absolute value 0 through 4 corresponding to each of the possible values. The SELECT statement uses the value in the accumulator to select one of the five cases, producing the appropriate response to the letters A through D, or an error response for the last case. Upon completion of the SELECT group, control returns to the DOWHILE where the last character typed is tested against the letter D. If X is not equal to the letter D, the iteration continues. Otherwise, the DOWHILE completes and control returns to the console processor.

The control structures presented in this section are representative of the forms which can be implemented. Additional facilities, such as the controlled iteration found in Fortran DO loops, or Algol **FOR** loops can be implemented using essentially the same techniques used for the WHEN

and DOWHILE. Further, subroutine parameter mechanisms which pass actual values to subroutines for assignment to formal parameters can also be defined with macro libraries. Note also that it would be relatively easy to include control structures for the stack machine given in the previous section, thus allowing machine independent programming of control structures as well as arithmetic operations.

10.4. Operating Systems Interface

In a general-purpose computing environment, macros are often used to provide systematic and simplified mechanisms for programmatic access to operating system functions. Throughout this document, the examples have shown various low-level calls to the CP/M operating system which implement function such as single character input, single character output, and full message output. In each case, the macros simplify the operations by performing the low-level register set-ups and calls which perform the function.

The purpose of this section is to introduce more comprehensive operating system interface macros, and specifically show a sample macro library which allows simplified diskette file operations for sequential “stream” input/output operations. The principal macros of this library which allow file access are listed below:

FILE set up a named file for subsequent disk operations

GET read a single character from a specific data source

PUT send a character to a specific data destination

FINIS terminate file access for a specific group of files

ERASE remove a specific diskette file

DIRECT search for a specific file on the diskette

RENAME rename a specific diskette file

Before introducing the macro library which performs these functions, the operation of each macro is described, followed by a simple example.

The **FILE** operation takes the form:

FILE mode,fileid,diskname,filename,filetype,buffsize,buffaddr

where the individual parameters of the **FILE** macro describe a particular file to be accessed in the program. The parameter values for the **FILE** macro are:

mode

- *infile* (input file),
- *outfile* (output file),
- *setfile* (set up file name for ancillary functions),

fileid file identifier for internal reference throughout the program.

diskname disk drive name (A, B, ..., P) containing the file being accessed, or empty if the default drive is being used.

filename the (up to eight character) file name of the diskette file being accessed; if "1" or "2" is specified, then the first or second default file name is used, respectively

filetype the (up to three character) file type of the file being accessed; if "1" or "2" has been specified for the filename parameter and an empty filetype is given, then the file type is taken from the selected default file name, otherwise the type is set to blanks.

buffsize the size (in bytes) of the buffer area used for this file; the value is rounded down to an integral multiple of the diskette sector size; if the rounding produces a result which is too small, or if the parameter is empty, then only one sector is buffered.

buffaddr the address of the buffer area to be used during accesses to this file; if empty, then the buffer address is assigned automatically.

The FILE statement

```
FILE INFILE,ZOT,A,NAMES,DAT
```

for example, sets up the file "NAMES.DAT" on diskette drive A for subsequent access. Internal to the program, this file will be referenced by the name ZOT. Further, the buffer address is assigned automatically, and the buffer size is set to one sector (normally 128 bytes). In general, larger buffers are useful in minimizing rotational delay on the diskette due to "missed sectors" during the file operations. If the "NAMES.DAT" file does not exist, an error message is sent to the console, and the program is aborted. An output file can be created using the statement

```
FILE OUTFILE,ZAP,B,ADDRESS,DAT,1000
```

for example, which creates the file "ADDRESS.DAT" on drive B for subsequent output, referenced internally by the name ZAP. In this case, the buffer size is set to 1000 bytes (rounded down to $7 * 128 = 896$ bytes), and the base address of the buffer is set automatically. The sample programs show alternative FILE options.

The GET macro invocation takes the form

```
GET device
```

where "device" specifies a simple peripheral or a diskette file defined by a previously executed FILE statement. The GET statement reads one byte of data into the 8080 accumulator from the specified device. The possible device names are:

key console keyboard input

rdr reader device

fileid previously defined file identifier given in a FILE statement

The following GET invocations perform the functions shown to the right below.

GET KEY read one keyboard character

GET RDR read one reader character (see *CP/M Interface and Alteration Guides* for **READER** entry point definition)

GET ZOT read one character from the file given by the internal name **ZOT** (i.e., the **NAMES.DAT** file if the above **FILE** statement had been executed)

The end of data can be detected in two ways: if the file contains character data, the end of file is detected by comparing the individual characters with the standard CP/M end of file mark which is a CTRL-Z (hexadecimal 1AH). The **GET** function also returns with the 8080 zero flag set to true if a real end of file is encountered so that pure binary files can be read to the end of data.

The **PUT** macro performs the opposite function from the **GET** macro. The **PUT** invocation takes the form:

PUT *device*

where “device” specifies a simple output peripheral or a diskette file defined previously using the **FILE** macro. The possible device names are

con console display device

pun system punch device

lst system listing device

fileid previously defined output file identifier

The following **PUT** invocations perform the functions shown to the right below:

PUT CON write the accumulator character to the console

PUT PUN write the accumulator character to the punch

PUT LST write the accumulator character to the list device

PUT ZAP write the accumulator character to the file whose internal name is **ZAP** (i.e., the **ADDRESS.DAT** file in the above example)

Note that the character in the accumulator is preserved during the invocation so that it may be involved in further tests or macro invocations following the **PUT** statement.

The **FINIS** statement is used to close a file or set of files upon completion of file access. In the case of an output file, the internal buffers are written to disk, and the file name is permanently recorded on the diskette for future access. The form of the **FINIS** invocation is

FINIS *filelist*

where “*filelist*” is a single internal name which appeared previously in a file statement, or a list of such file names enclosed within broken left and right brackets, and separated by commas. Although it is not necessary to close input files with the **FINIS** statement, it is good practice, since the file close operation may be required on future versions of the macro library. An example of the **FINIS** statement is:

FINIS ZAP

- write all buffers for the ZAP file, and record the file in the diskette directory; in the above example, the ADDRESS.DAT file is closed.

The ERASE macro allows programmatic removal of a diskette file given by the specified file identifier defined in a previous FILE statement. If the file identifier is not used in a GET or PUT statement, then the FILE statement can have the mode "setfile" which requires less program space than an "infile" or "outfile" parameter. Specific cases of the ERASE statement will be given in the examples which follow. In the simple case

ERASE ZOT

however, the file NAMES.DAT would be removed from the diskette, given the previous FILE statement which defines ZOT.

The DIRECT macro is used to search for a specific file on the diskette. Similar to the ERASE macro, the file identifier must be previously given in a FILE statement using one of the three possible file modes. The DIRECT invocation sets the 8080 zero flag to false if the file is present on the diskette. In both the ERASE and DIRECT macros, the file identifiers can reference file names and types with embedded "?" characters, similar to the normal CP/M "DIR" command, where the question mark will match any character in the file names being scanned. The macro invocation

DIRECT ZAP

for example, returns a non-zero flag if the file ADDRESS.DAT is present, and a zero flag if the file is not present, given the original FILE statement involving the ZAP file identifier.

The RENAME macro takes the form

RENAME *newfile*,*oldfile*

where "*newfile*" and "*oldfile*" are file identifiers which have appeared in previous FILE statements. The RENAME macro changes the file name given by *newfile* to the file name given by *oldfile*. Similar to the ERASE and DIRECT macros, the file identifiers "*newfile*" and "*oldfile*" must appear in previously executed FILE statements, but may have a mode of "setfile" if they are not used in GET or PUT macros. If the drive names for the *oldfile* and *newfile* differ, then the drive name of the *newfile* is assumed.

The sequence of macro invocations

```
FINIS    ZAP      ;CLOSE "ZAP"
ERASE    ZOT      ;REMOVE "ZOT"
RENAME   ZOT,ZAP  ;CHANGE NAMES
```

for example, first closes the ADDRESS.DAT file on drive B, then erases the NAMES.DAT file on drive A. The RENAME macro then changes the ADDRESS.DAT file to the name NAMES.DAT file on drive A.

Listing 10-72 shows the use of the `FILE`, `GET`, `PUT`, and `FINIS` macros in a working program. The purpose of this program is to read an input file, specified at the console command processor level as the first file name, and translate each lower case alphabetic character to upper case. The output is sent to the file given as the second parameter at the command level. Given that this program has been assembled, loaded, and stored as “`CASE.COM`” on the diskette, a typical execution would be

```
CASE LOWER.DAT UPPER.DAT
```

which causes the `CASE.COM` file to be loaded and executed in the transient program area. Before execution, the console command processor passes `LOWER.DAT` as the first default file name, and `UPPER.DAT` as the second file name (see the *CP/M Interface Guide* for exact details). Referring to Listing 10-72, the `CASE` program begins by initializing the stack pointer to a local stack area in preparation for subsequent subroutine calls which occur within the various macros in the `SEQIO` macro library. The first default file name is then taken as the `SOURCE` file, as defined in the first `FILE` macro. The second `FILE` statement assigns the second default file name as an output file with the internal name `DEST`. In both cases, the `FILE` statements open the respective files and initialize the buffer areas consisting of 2000 bytes (rounded down to a multiple of the sector size). Note that if the `UPPER.DAT` file already exists, the second file statement removes the existing file and creates a new `UPPER.DAT` file before continuing. In either case, the appropriate error messages will appear at the console if the files cannot be accessed or created in the `FILE` statements.

The `CASE` program’s main loop is shown in Listing 10-72 between the `CYCLE` and `ENDCOPY` labels. Each successive character is read from the `SOURCE` file (in this case, `LOWER.DAT`) and tested to see if the character is in the range of a lower case “a” to lower case “z”. If in this range, the character is changed to upper case. At the `NOCONV` label, the (possibly translated) character in the accumulator is sent to the console device using the “`PUT CON`” macro and then sent to the `DEST` file (in this case, `UPPER.DAT`). Looping continues back to the `CYCLE` label where another character is read and translated. Since the data file is assumed to consist of a stream of ASCII characters, the end of file is detected when a `CTRL-Z` is encountered. When this character is found, control transfers to the label `ENDCOPY` where the `DEST` file is closed using the `FINIS` macro. Again note that errors in writing or closing the `DEST` file will produce an error message at the console, and the program execution will be aborted immediately. Upon completion of the program, control is returned to the console processor through a system reboot (`JMP BOOT`).

0370          END

```

Listing 10-72: **Assembly Listing:** Lower to Upper Case Conversion Program

The SEQIO library macros assume that all file buffers are located at the end of the user's program, as shown in Listing 10-72. In particular, the label BUFFERS must appear as the last label in the user's program, and becomes the base of the buffers allocated automatically in the FILE statements. The actual memory requirements for the program can be determined using an "EQU" as shown in Listing 10-72, with a statement of the form

```
MEMSIZE EQU    BUFFERS+@NXTB
```

which produces the equated value 1270H at the left of the listing. In this particular case, the memory area beyond 1270H is not used by the program.

The macro library for SEQIO is shown in Listing 10-73, which constitute the most comprehensive macro library shown in this manual. The particular macro library contains an instance of nearly every macro facility available in MAC, and thus it is useful to read and understand the operations

contained in the listing. The discussion below of SEQIO outlines the general functions of each macro, but it is left to the reader to investigate the exact operation of the library.

The SEQIO segment shown in Listing 10-73 contains generally useful equates and utility macros. The label FILERR at the beginning becomes the destination of transfers upon encountering a file operation error and, since this is a SET statement, may be changed in the user's program to "trap" error conditions rather than rebooting. The use of FILERR is apparent throughout the macro library.

The equates which follow define the usual BDOS entry points and functions, along with the diskette sector size (@SECT), and special non-graphic characters (EOF, CR, LF, and TAB). The equates for @KEY through @LST are used in the GET and PUT macros to determine the source or destination device. The INFILE, OUTFILE, and SETFILE equates are used in the FILE macro as mnemonics for the file mode attribute.

Referring again to Listing 10-73, FILLNAM is a utility macro which is used in the construction of a file control block. In particular, it accepts a file name or file type along with a field size and builds a sequence of DB's which fill the name or type field with padded blanks. FILLDEF is again a utility macro similar to FILLNAM, but fills the file control block name or type field from the default file control block at @TFCB or @TFCB+16. FILLDEF is invoked to extract either the default file name (first 8 characters) or default file type (following 3 character field). Note that the FILLDEF macro constructs an inline subroutine to perform the data move operation the first time it is invoked and calls the inline subroutine (@DEF) upon subsequent invocations.

The last macro definition shown in Listing 10-73 is FILLNXT which is used to initialize two assembly time variables: @NXTB and @NXTD. @NXT13 is used to count the accumulated size of buffers as they are automatically allocated in the FILE statement, while @NXTD is used to count files in the FILE macro for later reference in GET and PUT statements. They are included within a macro so that they will be properly initialized in the two successive passes of the macro assembler. FILLNXT is invoked by the FILE macro where the expansion initializes @NXT13 and @NXTD. Note that FILLNXT then redefines itself as an empty macro so that subsequent FILE invocations do not reset the two counters.

A major utility macro, called FILLFCB, is shown in Listing 10-73. The primary purpose of this macro is to construct a file control block in the CP/M standard format, where FID is the file identifier, DN is the disk name, FN is the file name, FT is the file type, BS is the buffer size, and BA is the buffer address, as described in the FILE statement above. Recall that some of these parameters may be empty, causing default conditions to be selected. The FILLFCB macro begins by searching for a "1", or a "2" as the FN parameter, indicating that either default name 1 or 2 is to be selected for the file. Note that the IRPC loop involving ?C will result in a value of 1 for @C if either FN=1 or FN=2, and a value of 0 for @C if FN is not 1 or 2. The FILLFCB macro then selects

either the default name, or the user specified name along with the default or user specified drive number. The equate for FCB&FID then produces the address of the file control block for the file identifier followed by "DB 0" for the extent field and "DS 20" for the remainder of the file control block. The reader may wish to cross-reference the file control block format shown in the *CP/M Interface Guide* for exact formats.

```

Listing 10-73: **Library Source:** Sequential File I/O Library

The remainder of the `FILLFCB` macro, shown in the lower half of Listing 10-73, is devoted to storage allocation for buffer areas. The `@BS` variable is set to the buffer size after rounding and size checks. `FID&BUF` then becomes the address of the file's buffer area, and `FID&ADR` labels a "DW" containing this literal value. `FID&SIZ` becomes the literal size of the buffer, and `FID&LEN` labels a "DW" containing the literal size. `FID&PTR` is also allocated as a double byte which will subsequently hold the buffer index to the next character to get or put in the file. All of these values will be used in the file operations which occur later.

The principal file access macro, called `FILE`, is shown in Listing 10-73, and is used to set up the file control block, buffers, and access subroutines for a particular file. Similar to the `FILLFCB` macro, the parameters `FID`, `DN`, `FN`, `FT`, `BS`, and `BA` describe the particular characteristics of a file. The `MD` parameter, however, is present to indicate the file mode and must have the value 1, 2, or 3. The `FILE` macro begins by assigning the mode value to `FID&TYP` so that subsequent macros can determine the type of access for this file. The `FILLFCB` macro is then invoked to construct the file control block for this macro, and sets generally useful parameters for the file, as discussed above. The `FILE` macro then generates either the label `GET&FID` or `PUT&FID` for input and output files, respectively, followed by a subroutine which `GET`'s a single character or `PUT`'s a single character for this file.

In general, the `GET&FID` reads a single character from the input buffer and, when the input buffer is exhausted, fills the buffer area again in preparation for following `GET` operations. Upon detecting a real end of file, the `EOF` character is returned with the zero flag set. Similarly, the `PUT&FID` subroutine generated for output files stores the accumulator character into the output buffer at the next character position and, when the buffer is full, writes the sequence of sectors and returns to accept more output characters. In the case of an output error, the appropriate message is printed, and control transfers to `FILERR` which usually remains at `0000H`, causing a system reboot.

The generated code which follows the label `PSUB` in Listing 10-73 is used to initialize the file pointers to the proper positions for file access. The file extent and next record fields of the file control blocks are zeroed for both input and output files. In the case of an input file, the buffer index variable `FID&PTR` is set to the end of the buffer, causing an immediate read operation when the first character is read. In the case of an output file, the `FID&PTR` is set to zero, indicating that the next position to fill is the first character of the output buffer. If the file is an output file, any duplicate files are erased, and a new file is created. In both cases, the file is opened upon completion of the `FILE` operation, and the buffer pointers are set for the next `GET` or `PUT` invocation. Note that the `FILE` statement is “executable” in the sense that it must occur ahead of the `GET` or `PUT` statements for the file, and performs its function each time control passes through the `FILE` machine code.

The `FINIS`, `ERASE`, `DIRECT`, `RENAME`, `GET`, and `PUT` macros are shown in Listing 10-73. The `FINIS` macro, shown on the left, serves to empty the output buffers and close the file for output. Input files are skipped since no actions need take place to close an input file. The main purpose of the `FINIS` macro is to fill the remaining buffer segment (one sector size) with `EOF`'s, then write the partially filled buffers.

The `ERASE` macro accepts a file identifier or list of file identifiers and successively calls the `BDOS` to erase each file, while the `DIRECT` macro searches only for a single file given by the file identifier `FID`. In the case of the `DIRECT` macro, the non-zero flag is set if the file exists. No prechecks are made to see if the file exists before the `ERASE` operation takes place, although erasing a non-existent file is of no consequence. The `DIRECT` macro can, of course, be used to check if a file exists before the `ERASE` is executed if deemed necessary by the programmer.

The `RENAME` macro shown in Listing 10-73 allows a file to be renamed by accepting two file identifiers, denoted by `NEW` and `OLD`. These file identifiers must correspond to the `FCB` names created by `FILLFCB` in an earlier `FILE` invocation, and has the effect of renaming the `OLD` file to the `NEW` file name. This is accomplished within the `RENAME` macro through an inline subroutine, called `@RENS`, which is included the first time the `RENAME` macro is invoked. The inline subroutine moves the new file control block information (first 16 bytes) into the second half of the old file

name in the form required for a rename operation under CP/M (see the *CP/M Interface Guide*). The BDOS is then called to perform the rename function. Note again that there is no check to ensure the old file exists before the rename takes place.

The GET and PUT macros shown in Listing 10-73 are similar in structure: both accept a device or file identifier as the formal parameter DEV, and perform the corresponding input or output function on that device. If the device is a simple peripheral, the BDOS is called directly to perform the input or output function. If instead, the device name was created by a FILE macro, the corresponding GET&FID or PUT&FID subroutine is called to accomplish the input or output operation. Note that the accumulator is preserved (PUSH PSW) upon output to a simple peripheral within the PUT macro, while the save/restore sequence is performed within the PUT&FID subroutine if the destination is a diskette file.

Listing 10-74, shows the full expansion of a segment of the case conversion program of Listing 10-72 (using the “+M” assembly parameter). Listing 10-74 shows the invocation of FILE, followed by FILLFCB, again followed by FILLDEF. The @DEF subroutine is included inline, and the FILLDEF macro is redefined to exclude the subroutine. Upon completion of the FCB construction, the file parameters are generated, as shown in Listing 10-74, along with the beginning of the GETSOURCE subroutine. Note that the conditional assembly ignores the portions of this FILE macro expansion which are related to output files while including the machine code for the input SOURCE file. In each case, the “&FID” labels result in names with the prefix or suffix “SOURCE” in order to associate the generated labels with this particular internal name.

Listing 10-74 contains the end of the PUTSOURCE subroutine, followed by the machine code which initializes the file control block fields and buffer pointer. Upon completion of the FILE macro, the SOURCE file is ready for access. In particular, each call to GETSOURCE reads one more character into the accumulator. Due to the length of the expanded macro form, the remainder of the case translation program is not shown.

Listing 10-74: **Assembly Listing:** Sample FILE Expanded (“+M”)

In order to illustrate the facilities of the SEQIO macro library, two additional programs are given. The first, called PRINT, formats the output from the macro assembler for printing on the system line printer. The second, called MERGE, performs a simple merge operation on two diskette files. The PRINT program, shown in Listing 10-75, is executed under the console command processor by typing

PRINT *filename*

where “*filename*” is the name of a previously assembled program. PRINT assumes that there is a “PRN” file on the diskette, and possibly a “SYM” file on the same diskette drive. The PRN file is first printed, with a form feed at the top of each 56 line page. If the SYM file exists, it is also printed using the same formatting. If the files are successfully printed, they are both erased from the diskette.

Listing 10-75: **Assembly Listing:** Line Printer Page Formatting

Referring to Listing 10-75, the PRINT program begins by saving the console processor's stack, with the intention of returning directly to the CCP, without a system reboot. The input printer file is then defined with a FILE statement which specifies the internal name PRINT, and obtains the file name from the console command line. The file type, however, is set to PRN in this case. After performing an initial page eject, the program loops between the PRCYC (print cycle) and ENDPR (end print) labels by successively reading characters from the PRINT source, and writing to the printer through the LISTING subroutine. On detecting an end of file character, control transfers to the ENDPR label where the PRN file is erased from the diskette.

As shown on the left of Listing 10-75, the program then checks for the presence of the SYM file by invoking the FILE macro with a SETFILE mode. This creates the proper file control block for the input file with type SYM, but does not create buffers nor does it open the file for access. Following the FILE macro, the DIRECT statement performs a directory search and, if the file is not present, control transfers to the ENDLST (end listing) label where execution terminates.

If the SYM file exists, the program proceeds to perform another page eject, and then opens the SYM file for access. It should be noted that the third FILE macro (Listing 10-75) accesses the SYM file using the internal name SYMBOL, but shares the buffer areas of the PRINT file. This is possible since the PRINT file has been erased at this point in the program and thus the buffers are available for use.

If the SYM file is present, the program loops between the SYCYCLE (symbol cycle) and ENDSY (end symbol) labels where characters are read from the SYMBOL file and again sent to the printer through the LISTING subroutine. Upon detecting the end of file, control passes to the ENDSY label where the SYM file is removed from the diskette. If no errors occur, control eventually reaches the ENDLST label where the printer page is ejected. The entry stack pointer is then retrieved from OLDSP, and control returns to the console command processor, thus completing execution of the PRINT program.

The next program, called MERGE, is somewhat more complicated. The purpose of the MERGE program is to accept two file names as input, taking the general command form

MERGE *filename*

where "*filename*" is the name of a master file, with assumed file type of MAS, as well as an update name with assumed file type UPD. The files consist of text files with varying length records, starting with a six character numeric "sequence number" followed by textual material, and terminated with a carriage-return line-feed sequence. The lines of information in the master and update files are assumed to be in ascending numeric order according to their sequence numbers. The purpose of the MERGE program is to read these two files and "shuffle" the records together to form a new file consisting of numerically ascending sequence numbered lines.

Upon completion of the merge operation, the newly merged file becomes the new master file: update records are properly interspersed within the new master file

according to numeric order, and any update record which matches a master record results in replacement of the master record by the update record. Upon successful completion of the merge operation, the original master file is renamed to have the extension MBK (master back-up), the original update file is renamed to the type UBK (update back-up), and the newly created file becomes the new MAS file. In this way, the operator can return to the backup files in case of error so that the source data is not destroyed.

The MERGE program is shown in Listing 10-76. Utility subroutines are listed first in Listing 10-76, including the DIGIT subroutine which tests for valid decimal digits in sequence numbers. The IRPC which follows the DIGIT subroutine generates two distinct subroutines, called READU and READM for reading the update and master files, respectively. The generation of these two subroutines has been suppressed in the listing (see the \$+PRINT and \$-PRINT inline parameters) to keep the listing short. In general, these two READ subroutines fill their respective sequence number buffers from the input source so that the merge operation can take place based upon the current sequence number values. Upon detecting an end of file, the sequence number is set to 0FFH as a signal that the input source has been exhausted.

Listing 10-76: Assembly Listing: File MERGE Program

The utility subroutines shown in Listing 10-76 include SEQERR, WRITESEQ, and COMPARE. The SEQERR subroutine reports an error condition when a non numeric character is detected in the sequence number field. Although the error reporting is somewhat spartan, sequence errors are easily found using the TYPE command on the master or update file. The WRITESEQ subroutine sends the buffered sequence number addressed by HL to the new file. WRITESEQ is called whenever the source for the next record has been determined. The COMPARE subroutine is used to determine the next source record (master or update) by comparing the buffered sequence numbers from left to right while they are equal. If a mismatch occurs in the sequence number scan, COMPARE returns with the carry flag and zero flag set to indicate which file holds the next source record.

Execution of the MERGE program begins following the START label in Listing 10-76 where the update, master, and new files are defined. The UFILE and MFILE sources are defined with the

same buffer sizes (as determined by the earlier `USIZE` and `MSIZE` equates). Both take their primary name from the default value specified at the CCP level by the operator. The new file is created as a temporary, with name `TEMP` and type `$$$`, but will be altered upon completion of the program to become the master file.

The merge operation proceeds in Listing 10-76 as follows. First the `READU` and `READM` subroutines are called to fill the sequence number buffers. The loop between `MERGE` and `ENDMERGE` in Listing 10-76 is then repetitively executed until the merge is complete. On each iteration of this loop, the `COMPARE` subroutine is called to compare the buffered sequence numbers. If the update sequence number is smaller than the master sequence number, it is moved to the new file and data is copied from the update file to the new file until the end of the current record is encountered. Upon completion of the copy operation, the `READU` subroutine is called again to refill the update sequence number buffer.

If the `COMPARE` subroutine instead detects equal sequence numbers, control transfers to the `SAME` label in Listing 10-76 where master record is deleted. Alternatively, the `COMPARE` subroutine will cause control to transfer to the `MASLOW` label when

the master sequence number is low. In this case, the master sequence number and data record are copied to the new file in exactly the same manner as an update record.

Upon completion of the merge operation (end of file detected in both the update and master files), control transfers to the `ENDMERGE` label where the files are closed and renamed. Following the `FINIS` statement, the previous `MBK` file (possibly from an earlier execution) is erased so that the current master `WAS` can be renamed to the master backup (`MBK`). Similarly, any previous `UBK` file is erased, and the current update file is renamed to become the new `UBK` file. Finally, the new file (`TEMP. $$$`) is renamed to become the new master file (`MAS`) before execution is stopped.

Listing 10-77, Listing 10-78 and Listing 10-79 shows an example of the files which are involved in a typical merge operation. In this application, the sequence numbers control the ordering of a list of names which is updated periodically. The `NAMES.MAS` file is the original master (Listing 10-77), which will be updated by merging the `NAMES.UPD` file, shown in Listing 10-78. The merge operation is initiated by typing

```
MERGE NAMES
```

and, upon completion, produces the new `NAMES.MAS` shown in Listing 10-79.

The `SEQIO` library is typical of the interface one can construct to provide a higher-level interface between assembly language programs and their operating environment. Although the library shown here performs only simple sequential file input/output, one can construct more comprehensive libraries for random access based upon this library.

```

Listing 10-79: **Sample File:** Sample MERGE updated file NAMES.MAS

11. Assembly Parameters

Assembly parameters can be included when the assembly begins to control various assembler functions. In general, the macro assembler is initiated with the name of the source file, followed by the assembly parameters, indicated by a preceding dollar symbol “\$”. The parameters are indicated by single controls which denote particular functions. The letter or digit shown to the left below corresponds to the function shown to the right.

- A** controls the source disk for the ASM file
- H** controls the destination of the HEX machine code file
- L** controls the source disk for the LIB files (see MACLIB)
- M** controls MACRO listings in the PRN file
- P** controls the destination of the PRN file containing the listing
- Q** controls the listing of LOCAL symbols
- S** controls the generation and destination of the SYM file
- 1** controls pass 1 listing

Any or all of the above parameters can be included. In the case of the A, H, L, and S parameters, they are followed by the drive name to obtain or receive the data, where the drives are labelled A, B, ... , Z. By convention, the X disk corresponds to the user's console, the P disk corresponds to the system line printer (logical LIST device), and the Z disk corresponds to a null file which is not recorded. The following is a valid assembly parameter list following the MAC command and source file name

```
$PB AA HB SX
```

which directs the PRN file to disk B, reads the ASM file from disk A, directs the .HEX file to the B disk, and sends the SYM file to the user's console. Blanks are optional between parameter specifications.

The parameters L, S, M, Q, and 1 can be preceded by either + or - symbols which enable or disable their respective functions. These functions are listed below

- +L list the input lines read from the macro library (see MACLIB)
- L suppress listing of the macro library (default value)
- +S append the SYM to the end of the PRN output
- S suppress the generation of the sorted symbol table
- +M list all macro lines as they are processed during assembly
- M suppress all macro lines as they are read during assembly
- *M list only "hex" generated by macro expansions
- +Q list all LOCAL symbols in the symbol list
- Q suppress all LOCAL symbols in the symbol list
- +1 produce a listing file on the first pass (for macro debugging)
- 1 suppress listing on pass 1 (default)

The following is an example of a valid assembly parameter list which uses a number of the parameter specifications given above:

```
$PB+S-M HB
```

In this case, the PRN file is sent to disk B with the symbol list appended (no SYM file is created), all macro generations are suppressed, and the HEX file is sent to disk B with the PRN file.

Note that the M parameter can be optionally preceded by the "*" symbol which causes the assembler to list only macro generations which produce machine code, and is used to suppress the listing of the instructions which are produced (i.e., all positions beyond the hex fields are not listed). Under normal operation, the macro assembler lists only generations which produce machine code, along with the generated line.

Given that disk *d* is the currently logged drive, the macro assembler defaults these parameters as follows: the ASM and LIB files are assumed to originate on drive *d*, the HEX, PRN, and SYM files are sent to drive *d*, a symbol table is generated with LOCAL symbols suppressed (i.e., all symbols beginning with "??" are not listed), and macro lines which generate machine code are listed.

Note, however, that the filename following the MAC command can be preceded by a drive name, in which case the P parameter overrides the drive name, if supplied. Whenever a parameter is repeated in the assembly parameter specification, the last value is always assumed. Valid assembly statements are shown below, assuming the file to be assembled is called "sample".

```
MAC sample $PX+S-M
```

assembles the file sample.ASM with listing to the console, symbols at the console, and no listing of generated macros.

```
MAC A:sample $+S -m+q
```

assembles `sample.ASM` from disk A, creating `sample.PRN` (with appended symbols) on the currently logged drive, suppressing generated macros, and listing symbols which begin with the characters “??” in addition to the normally listed symbols.

```
MAC sample
```

assembles `sample.ASM` from the currently logged drive, creating `sample.PRN` along with `sample.SYM` (containing the symbol table) and `sample.HEX` which holds the Intel format “hex” file in ASCII form.

```
MAC sample $AB HA PB +Q +S +L *M
```

assembles the `sample.ASM` file from drive B, produces the file `sample.HEX` on drive A, with the `sample.PRN` file on drive B. The symbol table includes “??” symbols, the symbol table is placed at the end of the PRN file on drive B, the LIB files are listed with the PRN file as the LIB files are read, and the instructions which correspond to generated macro lines are not included (although generated machine code is listed).

In addition to the parameters shown above, the programmer can intersperse controls throughout the assembly language source or library files. Interspersed controls are denoted by a “\$” in the first column of the input line, where the form shown to the left below corresponds to the action given to the right.

\$-PRINT stops the output listing by discarding formatted lines

+\$PRINT enables the output printing when previously disabled

\$-MACRO disables generated macro lines, as in “-M” above

+\$MACRO enables full macro trace, as in “+M” above

\$*MACRO enables partial macro trace, as in “*M” above

Since MAC allows each line to be optionally prefixed by a line number, the “\$” control can be included directly following this line number, if desired.

12. Debugging Macros

In completing the discussion of the macro assembler, it is worthwhile considering common debugging practices used in developing macros and macro libraries. One technique, called “iterative improvement,” is often used in the design of programs, and is most useful in building macros. The basic idea of iterative improvement is that a small portion of the overall macro set is first implemented and tested before continuing to more complicated macros. In this way, errors can be isolated at each step as the macro evolve. Further, if errors occur in the macro generations after a small portion of the macro set has been improved, it is most likely the case that the error is being caused by the macros which were changed.

In the case of the Hornblower Highway System macro libraries, for example, iterative improvement was used to evolved the final macro library. In particular, only the simplest macros were first implemented, including the SETLITE, TIMER, and RETRY macros (see Section 10.1). Debugging facilities were then added to these macros so that the programs could be traced at the console. Upon successful testing of the basic macro facilities, the PUSH?, CLOCK?, and TREAD? macros where individually written, added, and tested, resulting in the final macro library.

At each step, the programmer can use the various assembly parameters to control the debugging information. If the macro generations are not producing the proper machine code, it may be necessary to obtain a full trace, using the “+M” option when MAC is started. If the program produces too much output with the full trace enabled, the programmer can use the “\$+MACRO” and “\$-MACRO” commands interspersed throughout the assembly language source program, resulting in fun macro generation traces only in the regions selected for debugging consideration.

If macro generation errors are caused by macro libraries, the programmer can use the “+L” parameter when MAC is started to cause the libraries to be included in the listing as they are read.

As a final consideration, it may be necessary to enable the first pass listing of the assembly language using the “+1” parameter. In this case, MAC will list the program as it is being read on the first pass as well as the second pass. Note, however, that the listing will contain spurious error messages on this pass which may disappear on the second pass. The principal purpose of the first pass listing parameter is to allow the programmer to view the macro generations on the two successive expansion passes to ensure that the assembler is processing the program in the same way in both cases.

If a particular macro expands improperly, and the source of the error is not evident after examining various traces, it may be necessary to remove the offending macro from the program and create an isolated smaller test case where the error is reproduced. Full traces can then be

examined to determine the source of the error and, after fixing the macro, it can be replaced in the larger program and retested.

13. Symbol Storage Requirements

The maximum program size which can be assembled by MAC is determined only by the symbol table storage requirements for the program. The symbol table itself occupies the region above the macro assembler in memory, up to the base of the CP/M operating system. Thus, the size of the symbol table depends upon the size of the current MAC version (approximately 12K program and data, plus 2.5K for I/O buffers) and the size of the user's CP/M configuration. In any case, the symbol table size is dynamically determined by MAC upon startup, and fills as symbols are encountered. In order to provide some insight regarding storage requirements, the basic item size for identifiers and macros is given below.

A name used as a program label, data label, or variable in a SET or EQUATE requires

$$N = L + 5$$

bytes, where L is the length of the identifier name. Thus, the statement

```
PORTVAL EQU 37FH
```

makes an entry into the symbol table which occupies

$$N = 7 + 5 = 12 \text{ bytes}$$

of symbol table space. Recall that LOCAL symbols take the form ??nnnn which generates a name of length $L = 6$.

Macro storage is somewhat more complicated to compute. The general form is given by

$$M = L + 7 + H + T$$

where L is the macro name length, H is the parameter header storage requirement, and T is the macro text storage requirement, computed as

$$H = P_1 + P_2 + \dots + P_n + n$$

where P_i is the length of the i th parameter name. The text length T is the number of characters in the macro body, including tab and end of line characters. Reserved symbols, however, are reduced to a single byte, instead of their multi-character representations. The jump, call, and return on condition operators, however, require their full character representations. Comments starting with double semicolon are not included in the character count. In fact, the comment line is "backscanned" to remove preceding tab or blank characters in this case. For example, the macro

```
LOADR MACRO REG,ALPHA ;FILL REGISTERRLF
    MVI REG, '&ALPHA'  ;;DATARLF
    ENDMRLF
```

contains a macro header, followed by two macro lines, where each line is written with tab characters (rather than spaces) and terminated by carriage-return line-feeds ($C_R L_F$).

In this case, the macro name length (LOADR) is five characters ($L = 5$), and the parameter name lengths are three characters (REG) and five characters (ALPHA), resulting in the parameter header storage requirement of

$$H = P_1 + P_2 + 2 = 3 + 5 + 2 = 10 \text{ bytes}$$

The first macro line contains a leading tab (one byte), the MVI instruction (reduced to one byte), another tab character (one byte), the operands REG, '&ALPHA', (twelve characters), and the end of line (two characters) for a total of seventeen bytes. Note that the comment, with the preceding tab, is removed from the line. The second line contains a tab (one byte), ENDM (one byte), and end of line (two characters) for a total of four bytes. Summing the textual characters, the total is $T = 21$ bytes. As a result, the total macro storage for LOADP is

$$M = L + 7 + H + T = 5 + 7 + 10 + 21 = 43 \text{ bytes}$$

No permanent storage is required for REPT's, IRPC's, or IRP's, although temporary storage in the symbol table is used while the groups are actively iterating. In particular, the characters contained within the group bounds (from the header to the corresponding ENDM) are stored in the symbol table in their literal form, with no reduction of reserved symbols to single bytes. Upon completion of the iteration, the storage is returned for other purposes. Similarly, active parameters for macro expansions require temporary storage in the symbol table which is returned upon completion of the macro expansion.

In any case, a symbol table overflow message will result if the total amount of free symbol table space is used up. As mentioned previously, the user can regenerate the CP/M system, up to the maximum memory space of the 8080 processor, to increase the symbol table area. Note that the "percentage" of symbol table utilization is always printed at the console at the end of the assembly. The form of the printout is

```
0hhH USE FACTOR
```

where *hh* is a hexadecimal value in the range 00 to FF, where 00 results from a near empty table, and FF is produced for a nearly full table. The value 080H, for example, is printed when the symbol table is half full. The programmer should keep note of the use factor as a particular program is developed in order to gauge the relative amount of free space as the program is enhanced.

In many of the examples shown in this manual, macros include inline subroutines which are generated at the first invocation and called upon subsequent invocations (see the TYPEOUT macro in Listing 7-15, for example). These subroutines can be included in the mainline program to reduce symbol table storage requirements, if necessary. In this case, the subroutines are

assumed to exist when the macro is invoked the first time, and thus are not generated by the macro.

14. Error Messages

When errors occur within the assembly language program, they are listed as single character flags in the leftmost position of the source listing. The line in error is also echoed at the console so that the source listing need not be examined to determine if errors are present. The single character error codes are:

- B** Balance error: macro doesn't terminate properly, or conditional assembly operation is ill-formed.
- C** Comma error: expression was encountered, but not delimited properly from the next item by a comma.
- D** Data error: element in a data statement (DB or DW) cannot be placed in the specified data area.
- E** Expression error: expression is ill-formed and cannot be computed at assembly time.
- I** Invalid character error: a non graphic character has been found in the line (not a carriage return, line feed, tab, or end of file); re-edit the file, delete the line with the I error, and retype the line.
- L** Label error: label cannot appear in this context (may be a duplicate label).
- M** Macro overflow error: internal macro expansion table overflow; may be due to too many nested invocations or infinite recursion.
- N** Not implemented error: features which will appear in future MAC versions (e.g., relocation) are recognized, but flagged in this version.
- O** Overflow error: expression is too complicated (i.e., too many pending operators), string is too long, or too many successive substitutions of a formal parameter by its actual value in a macro expansion. This error will also occur if the number of LOCAL labels exceeds 9999.
- P** Phase error: label does not have the same value on two subsequent passes through the program, or the order of macro definition differs between two successive passes; may be due to MACLIB which follows a mainline macro (if so, move the MACLIB to the top of the program).
- R** Register error: the value specified as a register is not compatible with the operation code.
- S** Syntax error: the fields of this statement are ill-formed and cannot be processed properly; may be due to invalid characters or delimiters which are out of place.
- U** Undefined Symbol: a label operand in this statement has not been defined elsewhere in the program.
- V** Value error: operand encountered in an expression is improperly formed; may be due to delimiter out of place or non-numeric operand.

Several error messages are printed at the console indicating terminal error conditions which abort the MAC execution. Whenever possible, the disk drive name, followed by the relevant file name is printed with the message.

NO SOURCE FILE PRESENT The source program file (.ASM) following the MAC command cannot be found on the specified diskette. Use the DIR command in the CCP to locate the source file.

NO DIRECTORY SPACE The diskette directory is full. Use the ERA command of the CCP to remove files which you do not need. There are often superfluous HEX, .PRN, and SYM files which can be removed.

SOURCE FILE NAME ERROR The form of the source file name is invalid, or not specified. The command form must be:

```
MAC filename $assembly parameters
```

where the “*filename*” is the (up to eight character) primary name of the source file, with an assumed file type of “.ASM” (which is not specified).

SOURCE FILE READ ERROR The source file cannot be read properly by the macro assembler. Use the CCP TYPE command to display the file contents at the console.

OUTPUT FILE WRITE ERROR An output file cannot be written properly, probably due to a full diskette. As in the directory full error above, use the CCP commands to erase unnecessary files from the diskette.

CANNOT CLOSE FILE An output file cannot be closed. The diskette may be write protected.

UNBALANCED MACRO LIBRARY A MACRO definition was started within a macro library, but the end of file was found in the library before the balancing ENDM was encountered. Examine the macro library using the TYPE command of the CCP, or use the “+L” assembly parameter, to ensure that the library is properly balanced.

INVALID PARAMETER An invalid assembly parameter was found in the input line. The assembly parameters are printed at the console up to the point of the error.
